There is no reason for separating the pneumonias into separate types in considering such factors as they share in common, as increased metabolism and reduction of available alveolar tissue for oxygen transfer. The demand for statistical evidence of the value of oxygen to relieve manifest signs of anoxia does not seem reasonable. No one would reasonably demand that there should be statistical evidence that patients who are suffering from anoxia of asphyxia due to submersion and are rescued shall be compared with those who are not. Because access of fresh air to the blood is in part cut off. Patients with cyanosis from pneumonia are in a condition analogous to one drowning. Anoxia may be prevented in pneumonia patients by increasing the partial pressure of oxygen in the air breathed. Patients suffering from severe unrelieved anoxia will not recover either with or without serum, and those

who do not develop immunity of their own accord or as the result of passive transfer of antibodies die even though anoxia is overcome. In pneumonia, specific serum assists recovery by neutralizing the specific soluble substance and prevents bacteremia which is often fatal.

CAN HEAT PRODUCE FRACTURE OF SKULL AND HEMORRHAGE AFTER DEATH?

To the Editor—Some time ago I was called on to perform an autopsy on a body which had been found on the prairie near this town on the embers of a small fire. The man had apparently been dead since the previous evening. The body had been badly burned the features being charred beyond recognition. The features of the face were covered by a burned cloth which appeared to be of the texture of a handkerchief and was firmly adherent to the face, nose, mouth and ears. There were several layers of this cloth. On removing it piecemeal I found that the mouth contained a large amount of blood which had been clotted homogeneously, apparently by external heat. It had a cooked appearance and contained no layers on cut surfaces as is the case with ordinary postmortem clots. The lower jaw had been fractured completely across between the second incisor and the canine teeth on the left. The right ear was filled with hard clotted blood. The nose also contained cooked blood and also unclotted bright red blood. The eyes were probably either gray or blue although absolute identification of the color was impossible. Extending vertically above the right ear was an area 6 by 4 inches covering the right parietal region where the scalp had been separated from the skull by blood which had the same cooked appearance. On the posterior aspect of the skull was a hole measuring 4 by 5 inches involving the occipital and posterior portions of both parietal bones. The bone edges of the aperture had been burned. The substance of the brain had been shrunken by the heat but was not burned beyond recognition as the gray and white matter could be distinguished. Between the dura and the skull was a layer of cooked blood from 1 to 2 inches in thickness. On removing the brain substance from the cranial cavity I found a basal skull fracture in the petrous portion of the right temporal and the sphenoid bones extending for about 1½ inches in the general direction of the right orbit. There was also a basal skull fracture involving the left temporal bone and extending into the foramen magnum. In my opinion this is undoubtedly a case of murder followed by burning in an attempt to destroy or disfigure the body. However, as no fragments of bone were found within the skull or in the vicinity of the body the question has been raised as to whether or not the large hole in the back of the skull could have been caused by burning. The body was found face on the fire. The county attorney has stated that he is of the opinion that intense heat within the skull is sufficient to cause a blowout of the bone. I have never heard of such a possibility and rather doubt its occurrence. In view of the broken jaw and the basal fractures of the skull as well as the other abnormalities I think that the man was killed by being severely beaten on the head and was thrown on the fire a short time later. It is also possible that chloroform or ether might have been administered to the victim in view of the several layers of cloth over the nose and mouth. I believe that only a short time or no time at all elapsed between his actual death and the contact with the fire because of the fact that the blood showed no layers as would have ordinarily occurred but was cooked throughout. Can you give me any opinions as to the effect of heat on the intact skull as to whether or not it might cause cracks in the skull or whether a large hole could be burned in the skull with no marked destruction of the cranial contents? Please omit name.

MD Montana

ANSWER—It would be impossible for heat to produce the fractures and the hemorrhages described in the question. The injuries to the head and face were produced during life.

SAWDUST AS CAUSE OF ALLERGY

To the Editor—I have under my care a butcher 40 years of age weighing 225 pounds (112 Kg.) with a diagnosis of bronchial asthma. He has had allergy tests for sensitivity and is markedly sensitive to house dust among other things. He has been addicted to alcohol but at the present time does not drink and is suffering from cirrhosis of the liver with its complications. He says that his allergy and consequent asthma is due to sawdust on the floor where he worked. Please advise me whether you have any case or cases on record in which sawdust aggravated or caused asthma. Where can I look for such cases? I should also like to know a method to prepare sawdust for testing the patient's sensitivity to it and how the test should be applied. Please omit name.

MD New York

ANSWER—Sawdust as a cause of bronchial asthma has been reported in the literature (Markin, L. E. *J. Allergy* 1:346 [May] 1930) but it is a rare cause. With a marked house dust sensitivity together with other reactions indicated in the query, one would hardly place much stress on the patient's opinion regarding sawdust as a cause of his trouble unless confirmation is obtainable clinically. A simple method for doing this is to have the patient cautiously inhale some of the clean sawdust before it is placed on the floor during a time when he is clear of symptoms. If he is sensitive to the material typical symptoms of hay fever will frequently occur in a few minutes. An attack of asthma however may not occur for hours after such inhalation. The nonspecific effect of inhaled dust particles (not house dust) in causing bronchial irritation and even asthma in such a procedure must how-

ever, be kept in mind. It is quite possible that the patient is not sensitive to sawdust but is sensitive to the various dangers, including feathers, that are to be found in a butcher shop.

A simple way of preparing material for testing such a case is to soak a handful of clean sawdust in a minimum amount of twentieth normal sodium hydroxide or of a 1 per cent sodium carbonate solution. The material should form a loose mush. After permitting it to soak an hour or two some of the fluid may be squeezed out and used for a cutaneous (scratch) test. Suitable controls should be used to determine the irritant properties of the extracted material. If no positive skin reaction is obtained by a scratch test a similar amount of sawdust should be shaken in a larger amount of distilled water or physiologic solution of sodium chloride for several hours. The supernatant fluid is poured off and filtered through a Berkefeld or Sertz filter for sterilization. This should then be tried intracutaneously in dilutions of 1:10,000, 1:1,000, 1:100, 1:10 and undiluted in a number of controls to determine its irritant properties. No more than 0.02 cc should be injected in each site. It may then be tried with caution (epinephrine solution should be on hand for a possible constitutional reaction) on the patient. The most dilute solution should be used first. If after twenty minutes, the skin reaction compared to the innate irritating properties of the material, is negative, the stronger solutions should be tried one by one. A positive skin reaction however is much less significant than a careful chemical trial as previously described.

PARKINSONIAN TYPE OF LETHARGIC ENCEPHALITIS

To the Editor—Will you please inform me in regard to the probable diagnosis, prognosis and treatment in the following case. A white woman aged 47 single whose previous health has been excellent had an attack of influenza in 1918 during the epidemic. The influenza was complicated by a train of severe nervous and mental symptoms which required hospitalization for several months and which was called sleeping sickness by the attending physician at that time. The patient made an apparently complete recovery at the time however and for a period of about thirteen years was free from any evidence of disease in the nervous system. About 1931 she gradually began to note that the left side of the body felt uncomfortable and was less dexterous. There was a sensation of unrest in the muscles. Tremor began fine in character of the hand and stiffness of the muscles then weakness and fatigability. The left lower extremity began to drag in the manner of hemiplegia. From 1931 the year of onset of these symptoms up to the present (five or six years) there has been a very insidious increase in the extent and degree of the tremor stiffness and especially muscle weakness. Note worthy however is the fact that on two occasions once in March 1936 and again in July 1936 the patient had a sudden complete relief from all symptoms for a period of several seconds or minutes. She described it as though a weight had suddenly been lifted off her. The patient is extremely intelligent and cooperative and fears to lose a position she holds and probable permanent invalidism. The oropharynx and cornea are sensitive no stigmas of hysteria are present. The blood pressure is normal. There is no headache or papilledema. Does lethargic encephalitis recur or become active after a lapse of years? How can one explain the sudden disappearance of symptoms if the condition is an organic one with the reappearance just as suddenly? Has artificial fever therapy, diathermy or intravenous vaccine been used in such cases? Has insulin shock therapy been tried? Are these forms of treatment contraindicated because of the presence of a possible active infection even though of low grade virulence? Please omit name.

MD New York

ANSWER—Lethargic encephalitis usually starts as an acute encephalitis. Occasionally there is no history of any previous acute stage. The patient has the parkinsonian type of chronic lethargic encephalitis. As far as it was possible to determine the patient in 1918 had recovered from her acute encephalitis several months after the onset. The sequelae or complications may occur immediately afterward or as is usually the case any time from three to twenty years after the acute attack with an entirely normal state of health during the interval. It is common in this disease entity to have periods of apparent complete disappearance of all symptoms. This occurs during sleep and while in bed. Under extreme emotional stimulation the subjective symptoms may also disappear. The masked facies however does not disappear unless the disease is a mild one. Artificial fever therapy, diathermy and intravenous vaccines of one type or another have been tried with no real success. Insulin shock therapy has not been tried. None of these forms of treatment are contraindicated except for the insulin shock therapy. The latter treatment requires scientific management because of the reactions the insulin may produce. The following drugs are used with some success: scopolamine hydrobromide 0.00065 Gm (1/400 grain) from three to five times daily; powdered leaves of stramonium from 0.03 to 0.05 Gm (one half to three-fourths grain) three times daily. The prognosis is good for life but not good for effecting a cure. This disease is incurable.

INTRASPINAL INJECTION OF ALCOHOL FOR PAIN IN CARCINOMA OF UTERUS

To the Editor—I have been informed that there is a preparation which can be injected into the spine for the control of uterine cancer to control pain, one injection controlling pain for from four to five weeks I am writing for information from you on this preparation

A L GREEN M D Milford Ill

ANSWER—The inquiry refers to the intraspinal (subarachnoid) injection of alcohol for the purpose of relieving the pain associated with malignant conditions of the female genitalia, especially the severe pain due to carcinoma of the cervix. The pain is usually controlled for many months rather than weeks. The technic for this procedure as described by J P Greenhill and H E Schmitz (*Am J Obst & Gynec* 31 290 [Feb] 1936) is as follows

No preliminary medication is given because we wish to observe the immediate effects of the injection. Most patients with advanced carcinoma of the cervix and other genital organs have much more pain on one side than on the other. The patient is placed on the side opposite to that where most of the pain is present. A pillow or pad is placed under her pelvis and side to elevate the sacral and lumbar portions of the spine. Her back is arched as much as possible, her body turned somewhat ventrally and the head lowered slightly. By placing the patient in this attitude we raise the sacrolumbar region of the spine to the highest level and at the same time make the posterior or sensory nerve roots lie horizontally. The anterior or motor nerve roots come to lie in a plane which is usually out of reach of the alcohol. Even if the motor nerves are not removed from the field of the alcohol as occurs in the cauda equina they are not often affected because sensory nerves are more susceptible than motor fibers to the effects of alcohol.

Some one should hold the patient in the proper position. A weak solution of iodine or other antiseptic is applied over the lumbar and upper sacral regions. An ordinary lumbar puncture needle with a stylet is used. The needle is injected into the fourth interspace just as for an ordinary lumbar puncture and we prefer not to use novocain in the skin before inserting the needle. After the needle is in the subarachnoid space as evidenced by the flow of spinal fluid 0.5 cc of absolute or 95 per cent alcohol is injected into the cerebrospinal fluid. For this purpose it is best to use a tuberculin syringe so as to be sure not more than 0.5 cc is injected. Furthermore the alcohol must be injected very slowly drop by drop taking about two minutes for the injection of the 0.5 cc. This will avoid a mixture of the alcohol with the spinal fluid. The alcohol rises immediately to surround the posterior roots because the specific gravity of alcohol is about 0.806 whereas that of the spinal fluid is 1.007. No attempt should be made to draw spinal fluid into the syringe to mix it with the alcohol because this is exactly what is not wanted. After the injection is made the needle is withdrawn and the puncture hole covered with sterile gauze and adhesive. Before the injection is completed the patient will complain that the upper leg feels numb or hot and that she cannot move the leg. The numbness is almost routinely experienced after the injection but disappears spontaneously after a few hours or few days in most of the cases. In spite of what the patient says concerning her inability to move the leg she can easily move it when requested to do so. At the same time the patient informs us of the numbness she also often tells us either voluntarily or in answer to our query that her pain has disappeared. The longer the patient is permitted to lie on her side the better the results. Hence we now keep our patients on their side for two hours after the injection. Then these women are permitted to get up and walk around. Some find difficulty in getting up from a chair because their leg is asleep. Sometimes the leg feels heavy and the patient experiences some trouble in walking up steps because the knee flexes readily. These sensations usually wear off in a few hours although in some women they last a number of weeks. Nearly all of our patients who were ambulatory went home within three hours after the injection and no ill effects have been observed from this procedure.

If the patient has pain on both sides an injection is made a week later with the patient lying on the opposite side. The same amount of alcohol is injected.

ELECTROGALVANISM FROM DENTAL FILLINGS

To the Editor—Will you kindly inform me whether a bridge made of platinum and white gold fitting just above two teeth inlaid with gold can cause an electrolytic action. The area at the side of the tongue adjacent to the bridge is complained of by the patient as producing queer annoying sensations. I should particularly like to know whether such a condition if prolonged could be related to the development of a malignant lesion.

M D Florida

ANSWER—Electrogalvanism in the oral cavity between dissimilar metallic restorations is a long established fact. Within recent years, research by different investigators and clinical reports published in various medical and dental journals have called attention to the possibility of annoying subjective symptoms and visible pathologic lesions such as localized ulcers and leukoplakias, with subsequent malignant growths, bearing a close relationship to the electrolysis between dissimilar dental restorations.

The degree of irritation and pathologic change depend on numerous factors, though chiefly on the relative positions which the different metals occupy in the standard electromotive series of metals published in college textbooks on physics or dental metallurgy.

In the case in question there is an upper bridge made of platinum and white gold. Immediately below there are two teeth with gold inlays. Pure platinum and gold are electro-potentially closely related, but in dental constructions for enhancing their value each is alloyed with other agents. Gold is bleached by the addition of nickel or silver. Most dental gold also contains from 10 to 15 per cent of copper to give it hardness. Both nickel and copper bear a comparatively wide electropotential relationship to pure gold or platinum, hence, when they are immersed in saliva, a good electrolyte, the elemental factors for a galvanic current exist.

An approximate measurement of current can be made with a delicate galvanometer or micro-ammeter. The most common symptoms of galvanic irritation in the mouth are usually first felt on the margins of the tongue, or an occasional metallic taste. Therefore, if other possible etiologic factors have been eliminated in this case, it is probable that the patient is being annoyed by electrogalvanism between his dissimilar dental restorations. If this conclusion is correct, the patient will be relieved if one or both constructions are removed and replaced with metals electropotentially balanced.

More explicit information on this subject may be found in

FUNCTIONAL UTERINE HEMORRHAGE TREATED AS ENDOCRINE DISTURBANCE

To the Editor—A white woman aged 24 has for the past six months been complaining of polymenorrhea. Menstruation commenced at the age of 13 without any difficulty. The menses were always regular, occurring at twenty-eight day intervals and lasting three or four days until the present trouble started. Bleeding for the past six months has occurred at irregular intervals varying from fourteen to twenty-one days with the duration increased to five or six days. The flow although not profuse is greater than formerly. The patient has no discomfort apart from some abdominal pains on the first day. Frequently in between the longer periods there occurs one or two days of bleeding. The patient is a thin woman of average build. The secondary sex characteristics are normally developed although the breasts are small. There are clinical evidences of a moderate secondary anemia. As the patient is a virgin rectal examination was made but it failed to reveal any pelvic disorder. The physical examination was otherwise normal in every respect. The onset of the present condition is related by the patient to the lifting of a heavy weight. She works in an institution where occasionally she is called to lift a weight of about 150 pounds. Her hours are long with little fresh air or recreation obtained. Her meals at the institution are of rather poor quality with the minimum of the essential elements. Her appetite is poor and she does not eat all this food. I have directed my treatment toward improving the hygienic dietetic and general health factors although her economic condition and her job limit this line. Is this therapy correct? If this fails, would endocrine therapy be indicated? Please give the rationale for the products recommended. A previous doctor advised sexual intercourse. Please comment.

M D New York

ANSWER—This patient evidently has functional uterine bleeding as evidenced by irregularity of menstruation from fourteen to twenty-one days with prolongation of the period to five or six days, and occasional bleeding more frequently. In the majority of cases of uterine bleeding of endocrine origin the anatomic basis of the condition is cystic hyperplasia of the endometrium. This hyperplastic condition of the mucosa is due to an excessive production of estrogen. Frequently a large cystic follicle is found in the ovary with absence of corpus luteum formation. These cystic follicles may continue to enlarge and secrete estrogen as long as the intracystic pressure does not cause atrophy of the granulosa cells. The continuous secretion of estrogen causes endometrial hyperplasia and vascularization. Cessation of production or decrease in the amount of estrogen allows the endometrium to regress with consequent hemorrhage, which may be excessive because of the hyperplastic endometrium. Cystic follicles may result from insufficient gonadotropic substance to effect ovulation or the ovarian tunic may be thickened and prevent rupture of the follicle. Corpus luteum cysts also may be responsible for functional uterine bleeding. Rectal examination in a virgin is rather unsatisfactory, especially in this condition of the ovary. The environment under which the woman works is of course not advantageous for the maintenance of good health and the correspondent's treatment directed toward improvement along these lines is commendable.

Gonadotropic substance from pregnancy urine or placenta has been recommended in these cases but is not altogether satisfactory in most instances. A gonadotropic preparation from the anterior pituitary may be more effective, but it must be used with care.

It might be well to give 150 units of gonadotropic substance from pregnancy urine or placenta intramuscularly every other day to the patient during the last half of her expected normal cycle each month over a period of three months and at the same time continue efforts to improve the unfavorable conditions under which she lives and works. The mild anemic condition, which is due to excessive bleeding, will improve with cessation of the flow, but she may be given any of the good preparations that are available for secondary anemia.

LATENT AND WASSERMANN FAST SYPHILIS

To the Editor—On a routine preemployment examination it was noticed in an applicant aged 29 that one pupil was slightly larger than the other. About seven years ago the patient had had an intercourse once without prophylaxis but did not later develop a penile lesion otherwise he always used a condom during copulation. Apparently he has not had a chancre rash or gonorrhea. Repeated blood Wassermann reactions however are four plus. The patient is a chauffeur. His general health is good except for frequent colds. Physical and neurologic examination (including ophthalmoscopy, visual acuity and colors is negative. Fluoroscopia by a cardiologist a spinal Wassermann test globulin and cell count were negative. A year and a half of continuous treatment has been given of a series of twelve injections of nearsphenamine 0.6 Gm at weekly intervals alternating with courses of bismuth salicylate 100 mg and bismocymol 100 mg beginning with a series of four weekly injections later lengthened to six and then to eight and also overlapping cessation of nearsphenamine. Iodides by mouth are also being taken. The patient is getting a balanced diet has sufficient sleep and does not drink or smoke. The Wassermann reaction at this time is still four plus and the Kahn reaction three plus. Has this patient syphilis? If so should further treatment be continued and for how long? Please omit name.

M D New York

ANSWER—Excluding the possibility that this patient may have either yaws or leprosy, both of which are unlikely in an individual who has spent his life in the temperate zone there is no doubt that he actually does have syphilis. Since his physical examination is completely negative except for slightly unequal pupils, and since there is no other clinical or laboratory evidence of cardiovascular or neuralsyphilis, he may be regarded as having latent syphilis and, in addition as being Wassermann fast. About 30 per cent of patients with latent syphilis have persistently positive serologic tests of the blood regardless of the type or amount of antisyphilitic treatment given.

The general management of the Wassermann fast situation is commented on in some detail in *Queries and Minor Notes* in *THE JOURNAL* Nov 4, 1933, page 1500.

In this particular patient who has already received a year and a half of continuous treatment, further medication may now be stopped except for a long course of heavy metal, i.e. from ten to twelve injections of a bismuth compound given at yearly intervals for the next five years.

The management of and the results obtained in latent syphilis are discussed by the Cooperative Clinical Group in a series of articles appearing in *Veneral Disease Information* (13 317 [Aug.] 351 [Sept.] 371 [Oct.] 389 [Nov.] and 407 [Dec.] 1932 and 14 1 [Jan.] 1933) and are more succinctly summarized in chapter 18 of Moore, J. E. *The Modern Treatment of Syphilis* Springfield, Ill. Charles C. Thomas, 1933.

In the discussion of the reference provided it will be noted that no stress whatever is laid on the presence of a persistently positive Wassermann reaction in adequately treated latent syphilis.

SULFANILAMIDE FOR GONORRHEA DURING PREGNANCY

To the Editor—A young woman five months pregnant has severe gonorrhea. So far as I can determine the tubes are not yet involved. Her general physical condition is good. Would it be safe to use sulfanilamide in this case so far as the pregnancy is concerned? If not what treatment would you advise? I have been using the Elliott method in other cases but I do not think it would be indicated here.

R S LANDER M D Victoria Texas

ANSWER—Sulfanilamide has been used to some extent in the treatment of gonorrhea in the male and female. It is however a new use for the drug. It has been proved useful for the treatment of streptococcal septicemia, but the evidence does not yet warrant its being unconditionally recommended for the treatment of gonorrhea. Experience with the drug in the treatment of patients during pregnancy is limited and physicians who employ it during gestation should use it with extreme caution. The effects of the drug on the fetus are not known and such conditions as acidosis, sulfhemoglobinemia, methemoglobinemia and even aplastic anemia which are reported to have followed its use would be especially serious during pregnancy.

Gonorrhea early in pregnancy is usually confined to the lower genital tract. It can be treated by rest in bed, plenty of fluids

and mild antiseptics. There should be no great difficulty in clearing up the infection prior to the onset of labor. The presence of the infection during pregnancy makes it especially necessary to institute prophylaxis of ophthalmia neonatorum at the time of delivery.

CYSTITIS WITH IMPOTENCE—ADDICTION TO HYPNOTICS

To the Editor—A man aged 53 has some burning sensation on urinating, he gets up once or twice at night. There is no history of gonorrhea. The teeth and tonsils have been removed. There is from 1 to 1½ ounces of residual urine. The prostate is slightly enlarged. Prostatic smear shows pus cells present. Sexual desire is diminished and the patient has a burning sensation at the time of orgasm and the thrill is missing. The patient has been married for twenty years there are no children. Kindly give a diagnosis. Do you know of any medicine I can give this man to relieve his symptoms and the pus from the prostate? Can he be brought back to a normal sex life? He is particularly interested in the latter question. A doctor has been taking second and pentobarbital sodium alternately every night for the past six months. He is healthy otherwise. He says he has developed a slight tolerance and they do not keep him under all night as they did in the start but he says he is wide awake all night if he doesn't take them and then the next day he is completely worn out and unfit to work unless he gets his sleep. Will these hypnotics hurt him? What would you suggest for him? Please omit name.

M D Illinois

ANSWER—The cystitis of the first patient is probably due to infection of the residual urine and may yield to ammonium mandelate (3 Gm every four hours) with restriction of fluid to 1 liter a day and avoidance of fruits and vegetables because of their alkalinizing tendency. This of course can be carried out only if such treatment does not increase the burning on urination. If it does, a preliminary course of alkaline diuretic therapy is desirable. The patient should refrain from sexual intercourse until he has a strong desire for it. In the meantime, improvement in the cystitis may bring about abolition of the burning sensation during orgasm, which may interfere with his experiencing the thrill.

The second patient has become habituated to barbiturates, and the hypnotics he is taking are commencing to lose even their symptomatic effect. It is obvious that the cause of the disturbance is not being remedied. The case is one for a rest cure under the care of an experienced psychiatrist, and preferably in a sanatorium. Physicians should ever remember the saying that 'a doctor who treats himself has a fool for a doctor and a fool for a patient.'

POLYNEURITIS OF PREGNANCY

To the Editor—A primipara in her seventh month at the present time began pernicious vomiting in her second month. Insulin, glycogen, the barbiturates and all reputed therapeutics were tried with varying success. At the end of the third month she was hospitalized with complete rest. At that time she showed a marked loss of memory. At the fifth month her memory had perceptibly improved but there was a very marked muscular weakness with improvement in the vomiting and an inability to walk which was attributed to almost complete lack of movements in her limbs while in bed. Now at her seventh month she is unable to walk owing to weakness in her limbs. She is fairly emaciated, the blood pressure is 100 systolic, has been 70 diastolic and for the past few weeks there has been a perceptible growth of fine hair on her face, body and limbs. It is very noticeable at present. No appreciable pigmentation is present in the skin or mucous membranes. She has a fair appetite, she does not vomit, the urine is normal and there is no elevation of temperature. I would like your opinion and recommendation of medication especially if you agree that this is a case of Addison's disease along with the pregnancy. I understand that there was an aqueous solution of adrenalin put out about 1930 by Swingle and Pfiffner but I have had no experience with it. If it would be long before this appears in *THE JOURNAL* I would appreciate anything you might offer as at any time her condition might be more serious. Please omit name.

M D Nebraska

ANSWER—This is a case of polyneuritis of pregnancy, which is a dietary deficiency disease. The clinical and pathologic picture is the same as that which occurs in alcoholism, infectious diseases and dietary deficiency diseases such as pellagra and beriberi. The disease usually occurs in the first or second pregnancy. The troublesome vomiting generally begins in the second month and, while usually mild at the beginning, becomes pernicious in type. Dehydration and emaciation result from the vomiting. The onset of paralysis is usually during the third and fourth months. The customary complaints are numbness, weakness and increased muscle pains generally in the lower extremities. Mental symptoms similar to Korsakov's psychosis appear at about the same time as the neurologic changes. The mortality of polyneuritis of pregnancy is about 25 per cent. This can be reduced considerably by early recognition of the disease and the administration of a proper diet or by the inter-

ruption of pregnancy Since the disease is due to lack of vitamin B, large amounts of this vitamin should be given as soon as symptoms of polyneuritis are recognized In fact, in all cases of hyperemesis gravidarum it is advisable to give vitamin B prophylactically For patients who do not respond readily to vitamin B, Strauss and McDonald recommend liver and liver extracts both by mouth and by injection If patients fail to improve under this therapy, the pregnancy should be terminated If this is done too late, it will not prevent death

Excellent articles have appeared, dealing with this subject

PURPURIC HEMORRHAGES

To the Editor—My niece has purpura haemorrhagica of four years' duration I have seen her immediately after a hemorrhage and have seen the blood spreading out under the skin which is painful She has an attack about the menstrual period each month and often has them between times She was told by three Dallas physicians that if the menopause was brought on by x-rays or radium she would get a cure Please give your opinion on bringing on the menopause for this condition

A M BOWDEN, MD, May Texas

ANSWER—As the bleeding tendency manifests itself between the periods as well as at the time of the menstrual period, there is not a sufficient relation between the bleeding and the menses to warrant x-ray sterilization Furthermore, because of the lack of definite data the exact type of purpura cannot be diagnosed No advice other than that of not producing the menopause by the x-rays can be offered

PREGNANCY AFTER MENOPAUSE

To the Editor—I am interested in the subject of pregnancy after the menopause Can you tell me where I can obtain information as to the percentage of women that become pregnant say two or three years after the cessation of the menses? B J McGOOGAN MD Morven N C

ANSWER—As far as is known there are no statistics concerning the frequency of pregnancy after the menopause There are, however, case reports of such occurrences De Lee (*The Principles and Practice of Obstetrics*, ed 5, p 19), mentions Renaudin's case of a woman who gave birth to a living child twelve years after the menopause, and of Kennedy's case of a woman who had five labors and one abortion after the fiftieth year Novak (*Menstruation and Its Disorders*, New York, D Appleton & Co, 1921) mentions Brickle's patient, who had had seven children up to 35 years of age Two years later her menses ceased entirely Eleven years after this she gave birth to another child

INJECTION OF BURSA

To the Editor—What substance if any when injected into a bursal cavity is effective in preventing further effusion? In other words is the injection treatment of bursae a recognized therapeutic measure?

M D Michigan

ANSWER—If a bursa is not inflamed and does not have a wide connection with a joint, solutions of 5 per cent sodium morrhuate or potassium oleate, injected after aspiration of the bursal fluid, are successful in a moderate number of cases After the injection, the area must be tightly bandaged or taped to help the obliteration of the sac. Usually a second and sometimes a third injection is necessary at weekly intervals Surgical excision is a delicate procedure but, when carried out with careful asepsis and hemostasis, is followed by excellent results Prior to its use, the injection treatment may be given a trial

TREATMENT OF ARTHRITIS DEFORMANS

To the Editor—Please give me the latest treatment of beginning arthritis deformans

M D, Ohio

ANSWER—There are a number of treatments that are at present in vogue in the treatment of arthritis deformans Many of them have not been tried long enough to furnish sufficient evidence as to the results Regarding the published results from the use of various sulfur preparations, concentrated iostrol and gold preparations, the correspondent is advised to consult the Third Rheumatism Review, 'The Problem of Rheumatism and Arthritis Review of American and English Literature for 1935' (*Ann Int Med* 10 754 [Dec] 1936)

Book Notices

The Use of Hearing Aids By A W G Ewing I R Ewing and T S Littler Reports of the Committee upon the Physiology of Hearing IV Medical Research Council Special Report Series No 219 Paper Price 9d Pp 40 London His Majesty's Stationery Office 1936

A great deal of careful investigation into the use of hearing aids is represented here. Improvements in the field of broadcasting have been carried over into the field of otology, so that by means of sound amplifying apparatus many of the deafened have been aided. The authors tested their deaf subjects in a number of ways and arrived at several interesting conclusions. By testing patients by a series of pure tones obtained from an audiometer, they found that a reliable index of the intelligibility of speech to the deaf could be obtained. They satisfied themselves that hearing aids are not, as many deafened persons believe, harmful to the user and do not cause further deterioration of the hearing. They emphasize the necessity of standardizing tests for the intelligibility of amplified speech and suggest that this is best done by means of an amplifier system properly constructed. They admit that impairment of hearing of certain types cannot at present be improved even with the best apparatus available and that hearing aids are still a disappointment to the patient and the physician. Even the best type of apparatus requires instruction in lip reading in many cases if the subject is to obtain the fullest results. Investigations like the one reported will provide the information that will lead to better and better results for the unfortunate deafened.

Family Care of Mental Patients. A Review of Systems of Family Care in America and Europe. Editor Horatio M Pollock PhD New York State Department of Mental Hygiene Albany N Y Cloth Price \$2.50 Pp 247 with illustrations Utica, New York State Hospitals Press 1936

This is an interesting volume dealing with an important phase of psychiatry. With the increase in the number of admissions into our state hospitals a tremendous building program is in the offing, and this brings the hopelessness of psychiatric cases to the public attention, perhaps to a greater extent than it should be. Dr Pollock has collected information from a number of American and foreign sources, pointing out that in the case of the feeble-minded and certain types of psychiatric patients a number of the more harmless can be farmed out in the smaller communities to live as a member of the family in private homes. This procedure is not new, for it has been carried out for a long time in Belgium and other parts of Europe, and as far back as 1860 it was proposed in Massachusetts. The present volume is rather more of a symposium than a single essay. Aiding Dr Pollock in compiling it were Dr Edgar A Doll of the Training School at Vineland, N J, Dr Harry A Laburt of the Harlem Valley State Hospital, Wingdale, N Y, Dr Philip Smith of the New York State Department of Mental Hygiene New York, Dr Charles E. Thompson of the Gardner State Hospital, East Gardner, Mass., and Dr Charles L Vaux of the Newark State School, Newark, N Y. All these contributors have had actual experience in the care of the insane or feeble-minded in families as well as in institutions, and the picture which they present as a whole, offers considerable hope in this plan for therapy and control of mental cases. The amazing results that the Newark State School in particular has had convinces one that more of the harmless defectives and the deteriorated mental patients who have no assaultive or sexual tendencies might well be placed out in families where too much would not be expected of them and where, perhaps, they could not only improve but also make some contribution to the family life. The book also raises the question why, if it is possible for these people to get along in

a private home, they could not get along in their own homes, and the answer, an important one, is predicated on emotional factors which have not as yet been looked into either by these authors or by others. The reader who peruses this book will gain some realization of what is being done in this country as well as in Belgium, France, Germany, Hungary, Scotland and Switzerland and will probably be inspired to urge that more family placement of mental patients be instituted. Some of the chapters give specific directions and instructions in administering this technique. Certainly there would be a saving in money and hospital space, more of the patients would be social contributors rather than drains on the community pocketbook, and in many cases the outlook would be distinctly improved. As a means of educating the community as to the harmlessness of many of the insane, this type of care of mental patients is worthy of deep consideration. One can only urge that this book be carefully studied by those who have to do with the problem of the care of mental patients.

Quelques vérités premières (ou soldisant telles) en chirurgie infantile Par L Ombrédanne professeur à la Faculté de médecine de Paris Col lection publiée sous la direction de M L Ombrédanne et N Flessinger Paper Price 24 francs Pp 85 Paris Masson & Cie 1936

This little volume, entitled "Some Fundamental Truths (or So-Called Ones) in the Surgery of Children," appears as one of a collection of monographs published under the editorial direction of Louis Ombrédanne and Noël Flessinger. The former, well known in this country through his "Précis clinique et opératoire de chirurgie infantile," is the author of this contribution, which consists of a great number of extremely practical facts of surgical diagnosis, differential diagnosis, surgical indications and treatment of surgical conditions in infants and young children. These facts have been accumulated from the author's extensive experience in children's surgery and he presents them as maxims, much in the manner of Napoleon's maxims of war. They are presented in six chapters. Chapter I deals with generalities—anesthesia, postoperative complications, fractures and epiphyseal separations, burns, diseases of bone, and tumors. The remaining chapters present the facts regionally, chapter II dealing with the face and neck, chapter III with the skull, brain, spinal column and spinal cord, chapter IV with the thorax and abdomen, chapter V with genital organs and chapter VI with the extremities. The author points out the differences one must be acquainted with in the surgical handling of infants and young children in various conditions, from that which is proper in adults. He also points out conditions that may be ruled out diagnostically, in various age groups, for example, that fractures are not rare even in the new-born—that the causal trauma may pass unperceived—the person caring for the infant may have let him fall without reporting the fact and such fractures often are first noticed as an enormous callus about the clavicle or femur. Do not think of a sarcoma in case of an infant of 3 weeks or 3 months. Try to recall how long this particular member has been inert. Then take a roentgenogram and this will clinch the diagnosis. Again, with regard to infantile scurvy he says that this does not occur before the age of 6 months. It does not heal after the age of 1 year. He points out similarly that one does not observe infantile paralysis (poliomyelitis) until after 6 months of age.

In considering the differential diagnosis between osteomyelitis and tuberculosis of bone, without perforations, he advises examination of the regional lymph nodes. Adenopathy is absent in osteomyelitis, it is constant in tuberculosis. He says that a positive cutaneous tuberculin test is valueless in infants. A definitely negative result on the contrary, is of considerable diagnostic value (ruling out tuberculosis). He points out that it is never wise to attempt surgical correction of a harelip soon after birth, the optimal period being after three to four months. He emphasizes that one should be careful in arriving at a diagnosis of congenital hypertrophic pyloric stenosis in an infant less than 15 days or more than 3 months old. He reduces the diagnosis of intussusception to a mathematical equation "signs of occlusion + passage of blood by rectum = intussusception. If a child 5 or 6 years of age passes red blood rectally without any signs of intestinal obstruction, it is a waste of time to think of any other cause than rectal polyp. Tuberculosis of the hip joint reaches the height of its frequency curve in the tenth year, whereas Pott's disease, which is still commoner, reaches its peak at 5 years of age.

The book contains a wealth of information that is of great value to all who have to do with child surgery. Although there is no alphabetical index, the table of contents, being arranged regionally, makes it easy to find the information desired. The volume can be highly recommended as authoritative and clinically practical.

The Human Machine. By John Yerbury Dent. Cloth. Price \$2.50. Pp. 299. New York: Alfred A. Knopf, 1937.

In spite of the fact that on the jacket of this book appear recommendations from H. G. Wells and Bertrand Russell, it is, to the American psychiatrist, a collection of unsubstantiated clichés. The publisher says that it is supposed to explain the basic mysteries of human behavior and that its author is a scientist—a distinguished English physician. What that rather prejudiced sales talk really means is that the author summarizes the simpler ideas of human genetics, gives a simple explanation of nervous integration, more or less stressing the elementary physiology of the special senses and the reactions of lower animals, and presents a superficial personal reaction toward suggestion, memory, habit and forgetfulness. A number of more or less unrelated psychologic material is collected in a chapter called "Conflicting Reactions," and some other chapters describe naively neurotic reactions. He believes in the somewhat questionable inhibitory theory of the causation of sleep and in the short chapter discusses some of the physical adjuncts of that state. Apparently Dr. Dent has done some hypnotizing—he calls it "selected inhibition"—and tells about a few cases that he has had. A knowledge of the work of Hull and others who are thorough modern students of this field is utterly lacking, and one can say but little about his criticism of psychoanalytic treatment. Some of the features which he brings out in criticizing psychoanalysis are justified, but his logic in explaining this criticism is questionable and shows a tremendous amount of affect which invalidates the whole chapter. One can safely say that the author goes further past the landmarks of logic in condemning psychoanalysis than even its more fervid and clear thinking advocates go in the opposite direction. All in all, while it may suit lay readers in some other country, this book will probably prove to be misleading to the initiated and aggravating to the trained psychiatrist in America.

The Exploration of the Inner World. A Study of Mental Disorder and Religious Experience. By Anton T. Bolsen. Research Associate in the Psychology of Religion and Chaplain the Elgin (Ill.) State Hospital. Cloth. Price \$3.50. Pp. 322. Chicago & New York: Willett Clark & Company, 1936.

The author is a minister who was a mental patient and who, since recovery, has devoted his life to working with mental patients in state hospitals and elsewhere. In this volume he has made a thorough study of the interrelationship of mental disease and religion, and the point of view which he takes is less that of the formal sectarian and more that of the understanding psychologist or, at least, psychologically and theologically trained person. The book is not a small volume and there is a great deal of theological material and much of the author's personal affective thinking confined within its covers. He approaches the subject rather emotionally, yet because of his consistent contact with experienced psychiatrists of several schools he has a good deal of insight into the problems of the mental patient. Some of the volume is highly theoretical but, on the other hand, there is much material treating of the cases he has seen, in which he makes comparisons of clinic types, classifications being used which he himself has devised. He interprets some of the religious tendencies and symptoms exhibited by mental patients. There are chapters devoted to Paul of Tarsus and George Fox, the founder of the Society of Friends. He points out some of their mental mechanisms and also describes how they would have been treated had they come into the hands of members of the various schools of mental healers. In later chapters he deals with the influence of the Christian religion in the sense of the teachings of Christ and their interpretation on conduct, character and feelings of guilt. He devotes one chapter to theology, which he calls the queen of the sciences, and approximately the last third of the book is devoted to the practical application of religion in psychiatry. He presents a chapter on the foundations of spiritual healing, describes some of his experiences while working with the mentally ill, and devotes a chapter to the distinctive task of the

minister of religion. At the end of the book there is a glossary which contains a number of good definitions of various psychiatric, sociological and psychologic terms but which is not alphabetized. The book is undoubtedly interesting. It contains ideas for those who are equipped by religious training to understand them, and perhaps some psychiatrists may find in it an explanation of how best to make use of the chaplain of their mental institutions. The book cannot be condemned, certainly, for it contains a mass of fascinating and enlightening material, but it is so highly interpretative that an assessment of its value would be determined entirely on the emotional and religious background of the reader, be he psychiatrist, physician, theologian or layman.

Über die Ernährung des Säuglings. Von Professor Dr. Hans Beumer. Direktor des Universitäts-Kinderklinik in Göttingen. Second edition. Paper. Price 2 marks. Pp. 40 with one illustration. Leipzig: Georg Thieme, 1937.

In the first half of this instructive pamphlet on the feeding of normal infants, Professor Beumer reviews briefly the well known one-third, one-half and two thirds cow's milk dilutions and other milk modifications in vogue on the continent during the past twenty-five years. The second half is a rather convincing dissertation on the virtues of lactic acid whole milk. In 1920, after Viennese pediatricians had shown that healthy infants can tolerate undiluted cow's milk enriched with carbohydrate, Beumer began to use the undiluted milk. In his first formula, 2 per cent flour (cornstarch, rice flour or wheat flour) and from 3 to 6 per cent sugar (nährzucker or saccharose) were added to the milk before boiling. Klotz was the first to add lactic acid to cow's milk. In 1923 Marriott showed that young infants can tolerate lactic acid whole milk for long periods. Others soon tried citric acid, hydrochloric acid, orange juice and lemon juice in place of lactic acid. Although excellent lactic acid powdered milks are on the market, the price makes them prohibitive for many families. To add one lactic acid tablet (acelette) for each hundred grams of milk is more economical, and mistakes are not so likely to occur as when mothers are entrusted with lactic acid. Saccharin may be added to sweeten the sour milk. Infrequency of stools when the infant is on lactic acid milk is harmless. In extreme cases saccharose may be substituted for nährzucker, if the condition is not relieved, a tablespoonful of malt extract may be added to the daily formula. If anorexia should occur in an infant on lactic acid milk, the cause should be determined. When diarrhea occurs in an infant on feedings other than lactic acid milk the transition to the acid milk should be gradual. Skimmed lactic acid milk may prove especially useful in cases of eczema.

The Cure of High Blood Pressure by Respiratory Exercises. By Lothar Gottlieb Tirala. M.D., Ph.D., Professor of Medicine, University of Munich. Authorized Translation by Freda Douglas and Albrecht Douglas. M.D., Ph.D., Boards. Price \$1.25. Pp. 71 with 13 illustrations. New York: B. Westermann Company, Inc. [n. d.]

This small, highly personal monograph expounds the views of the author concerning the etiology, pathogenesis and therapy of hypertensive arterial disease. The basic physiologic facts are sound, but the interpretations of these facts are adapted to suit a theory. The author contends that acidosis is a primary factor in the causation of hypertension and thus that deep breathing exercises for five or six minutes from two to five times a day are curative through improved aeration and bettered elimination of carbon dioxide. The thesis is not convincing. There are some curious applications of logic, for example, the fact that hypertension is rare among professional singers in Munich is cited as proof of these contentions. The specific cases cited are unimpressive, to better the apparent results Tirala clings to the long discarded axiom that the normal arterial tension is 100 plus the age. The resulting figures are far too high. He also advocates a purely vegetarian diet and states that sexual activity should be uncurbed as repression upsets the chemical equilibrium. Constipation is said to play an important part in the etiology of high blood pressure, these concepts have long been discarded here. The monograph is thought provoking in places, but the general impression is that Tirala is so thoroughly convinced of his theory that he attempts to make the facts fit the theory. Scientifically the book is disappointing.

Vitamins in Theory and Practice By Leslie J Harris ScD Nutritional Laboratory University of Cambridge and Medical Research Council Second edition Cloth Price \$3 Pp 242 with 66 illustrations New York Macmillan Company Cambridge University Press 1937

Although the first edition of this book was printed in December 1935, it has been necessary, as the author points out, to subject the text to considerable revision for the second printing. During the year 1936 vitamin B₁ became chemically identified and synthesized, and the recognition of riboflavin and other factors as important constituents of the vitamin G complex became clear. Readers will find this little volume packed with up to the minute information on the vitamins. The book is noteworthy because of the number of new and interesting illustrations and because of the readable and authoritative way in which the subject is presented. One may see for example, a facsimile of a page from the book by Sir Richard Hawkins published in 1593 describing the symptoms of scurvy, a picture of Captain Cook and a reproduction of a page from Lind's treatise on scurvy, and illustrations showing the petechial hemorrhages and bleeding gums of scorbutic patients. Each of the important vitamins is described briefly and yet adequately. There are numerous anecdotes regarding the contributions of modern research workers, so that the reader obtains what might be described as a personal knowledge of the subject. The final chapter takes up the practical question of what to eat and affords a number of suggestions.

A Hand Book of Ocular Therapeutics By Sanford R Gifford MA MD FACS Professor of Ophthalmology Northwestern University Medical School Chicago Second edition Cloth Price \$3.75 Pp 341 with 60 illustrations Philadelphia Lea & Febiger 1937

The author prefaces the second edition of his popular textbook on ocular therapeutics by stating that he has modified certain opinions and that the efficacy of certain new preparations and procedures has been sufficiently proved clinically to justify their inclusion. But the real reason for a second edition within four years is the wide demand for the book. The original book has been enlarged and includes a full discussion of the use of vitamins and glandular extracts, of the therapeutic use of heat and cold and of certain ocular conditions not described in the first edition. The chapter on physical therapy has been rewritten. The illustrations have in certain instances been replaced by ones the author considers better. Although this is essentially a one man book, the personal pronoun does not appear. The arrangement in the sequence of the chapters is orderly, for in the beginning various therapeutic measures are discussed and in the last half the application of these measures in cases of ocular disease is described. The discussion of therapeutics is based on the extensive personal experience of the author. The book is one of the foremost American textbooks and should form an essential part of every ophthalmologist's library.

The Blood Groups of the Bantu of Southern Africa By Ronald Elsdon Dew MB ChB Thesis approved for the Degree of Doctor of Medicine in the University of the Witwatersrand Johannesburg Publication of The South African Institute for Medical Research No XXXI Vol VII Edited by the Director Paper Pp 217 300 Johannesburg The South African Institute for Medical Research 1936

In this monograph the author presents the results of blood grouping tests on ten different groups of 500 individuals each from ten Bantu tribes of southern Africa. His observations demonstrate that the Bantus are not homogeneous, since there are distinct and in some cases marked serologic differences between the various tribes. His results seem to indicate that the Bantus are more primitive serologically than other black races examined up to the present time. This monograph also contains a review of certain aspects of the technique of blood grouping and the heredity of the blood groups. On the whole, it is written in an intelligent and interesting fashion. Unfortunately the author does not seem to be thoroughly familiar with the more recent literature but this handicap is compensated by his command of mathematics and his critical and intelligent presentation. In discussing the theory of von Dungern and Hirsfeld, he presents it as if heredity depended on two completely linked pairs of genes, whereas the conception of the originators of the theory was that the blood groups are transmitted by means of two independent pairs of genes situated in different chromosomes. This misconception is not of great

moment, however, since the theory of von Dungern and Hirsfeld has been disproved and the Bernstein theory of heredity, which is now generally accepted, is accurately presented in the monograph.

Agnosia Apraxia Aphasia Their Value in Cerebral Localization By J M Nielsen BS MD Associate Clinical Professor of Medicine (Neurology) University of Southern California With the assistance of J P FitzGibbon AB MD Resident in Neurology Los Angeles County Hospital Los Angeles California Cloth Price \$3 Pp 210 with illustrations Los Angeles The Los Angeles Neurological Society, 1936

This is an excellent treatise on agnosia, apraxia and aphasia. The author had the good fortune of having Dr Samuel D Ingham, a keen neurologist, as an adviser as well as a teacher. The work is based on a clinical study of 240 cases with twenty-five necropsies, thirteen surgical verifications and two roentgenologic corroborations. Because of gross errors and unwarranted conclusions in the old teaching Nielsen does not believe that the idea that aphasia can be of diagnostic value in cerebral localization should be discarded for the psychologic point of view. He shows where neurosurgical removal of portions of the brain has given confirmatory evidence to the old doctrine. He feels that a diagnostic method should not be permitted to fall into disrepute merely because it is difficult. The book is divided into three parts. Part I includes an introduction, the author's concept of eugnosia, eupraxia and euphasia, the method of presentation, agnosia, apraxia, aphasia and miscellaneous terms. Part II includes a method of examination of the patient, with presentation of cases and conclusions. Part III includes an alphabetical list of symptoms with synonyms, annotations and epitomized value in cerebral localization. There is a large bibliography. This book should be in the library of every neuropsychiatrist.

Chemistry of Food and Nutrition By Henry C Sherman PhD ScD Mitchell Professor of Chemistry Columbia University Fifth edition Cloth Price \$3 Pp 640 with 38 illustrations New York Macmillan Company 1937

A former reviewer wrote that the previous edition of this textbook on nutrition deserved an enthusiastic welcome. So much has been accomplished in the last several years in the field which this book covers so well that the present edition is more than welcome. As before, the subject is concisely discussed in a simple but authoritative manner that conveys a good general understanding of the subject. The present volume includes practically all the important newer discoveries and is just as indispensable for workers in nutrition as were earlier editions.

Das Geschlechtsleben Seine Bedeutung für Individuum und Gemeinschaft Von Carl H Csallner Der Arzt als Erzieher Heft 73 Boards Price 1.58 marks Pp 81 Munich Verlag der Ärztlichen Rundschau Otto Gmelin 1937

Csallner considers the sexual function as a natural and ordained part of human existence, the proper exercise of which makes for the welfare of the individual and the best interests of human society. It is only because of prudery and false sentiment that the sex relationship has been surrounded with mystery and shame. The binding marriage is the natural way of satisfying the full sex life. So called free love is strongly condemned not only because of its effects on the individuals concerned but because it is inimical to the regulations of human society and to the race. The tragic position of the unmarried mother and of the fatherless child is stressed, also the illusion of the double moral standard for man and woman. The finest racial characteristics, the author points out are encouraged and flourish under a state of settled, regulated marriage. The foregoing views are set forward in fifteen short chapters in this little monograph.

Modern Discoveries in Medical Psychology By Clifford Allen MD MRCP DPM Psychotherapist to the Institute of Medical Psychology London Cloth Price \$2.75 Pp 280 New York & London Macmillan & Co Ltd 1937

This is an excellent account of the development of medical psychology from Mesmer to Pavlov. The work of these two investigators and that of Janet, Morton Prince, Freud, Adler, Jung and Kretschmer is considered at length, with a complete review of their publications and an estimate of the worth of their work. Short bibliographies are given at the end of each chapter. The book is written in a clear, readable manner and

seems to be the best historical account of this field of medicine that has appeared in English. Although leaning toward the side of psychoanalysis, the author is extremely fair minded and points out the value of the work of others besides the great contributions of Freud. The one lack is a general final chapter, which is needed to summarize the entire book. The volume may be safely put in the hands of a medical student or a general practitioner, and an intelligent layman would not find it beyond his comprehension.

Études sur le spina bifida. Par Jacques Leveuf, professeur agrégé à la Faculté de médecine de Paris. Avec la collaboration de MM. Ivan Bertrand, directeur à l'Ecole pratique des Hautes Études et H. Sternberg, assistant de la clinique orthopédique de l'Université de Vienne. Préface du Professeur G. Roussy. Paper. Price 75 francs. Pp 330 with 176 illustrations. Paris: Masson & Cie 1937.

This book on spina bifida, by Leveuf in collaboration with Bertrand and Sternberg, is one of the most complete studies on the subject. It is divided into the following parts: definition, pathologic anatomy and etiology, clinical study, clinical forms and prognoses, spina bifida occulta, pathogenesis, treatment, treatment of hydrocephalus, incontinence of urine and paralysis and deformities of the extremities, study of the end results and conclusions. The entire work is brilliantly done and critically analyzed with regard to eighty cases that were observed personally. The pathology, symptomatology, pathogenesis and operative procedures are described in detail. The various associated symptoms and sequelae of spina bifida are adequately discussed. Both Bertrand's and Sternberg's chapters on malformations add greatly to the value of this book. There is an ample bibliography. This book is highly recommended to all neurologists, neurosurgeons and orthopedic surgeons.

Going to Make a Speech? By E. St. Elmo Lewis, Counsel in Consumer and Trade Relations. Cloth. Price \$3. Pp 359. New York: Ronold Press Company 1936.

The author, who is an experienced speaker, has evidently given considerable thought to the preparation of the address, the nature of the audience, the peculiarities of speeches to be made on various occasions, and many similar problems with which the average speaker is concerned. His advice in general is excellent and the examples he has chosen from the available literature on the subject are exceedingly well selected. To any one who feels that a book of advice can help him in doing the job of public speaking better, this book is as good as any that can be recommended.

The Operations of Surgery. By R. P. Rowlands and Philip Turner. B.Sc. M.S. F.R.C.S. Consulting Surgeon to Guy's Hospital. Volume II. The Abdomen. Eighth edition. Cloth. Price \$10. Pp 998 with 514 illustrations. Baltimore: William Wood & Company 1937.

The second volume of this well known English guide to operative surgery deals essentially with operations on the abdominal and genito-urinary organs. Though it presents chiefly the work and methods used in Guy's Hospital, more than one technic is usually given for any one procedure. The technic is described in step by step detail in simple, clear style and is well and adequately illustrated. Great stress is laid on the indications and complications, as well as on errors that may occur. The material is accurate and up to date. This book is a worthwhile addition to the library of any surgeon.

Take Care of Yourself: A Practical Guide to Health and Beauty Stressing the Proper Way to Use and the Prudent Way to Buy Home Remedies and Cosmetics. By Jerome W. Ephraim. Foreword by Logan Clendening, M.D. Cloth. Price \$2. Pp 287, with 18 illustrations. New York: Simon & Schuster 1937.

This combines elementary high school physiology, the old family "doctor book" and the buyer's guide in one volume. In the introduction Mr. Ephraim makes a point of the fact that the book is not an expose. Dr. Clendening, who contributes the foreword to the volume, also considers debunking a vulgarity. Because of this conservative attitude, the style frequently lacks force. There is, however, much valuable information contained in the eighteen chapters regarding the skin, cosmetics, antiseptics and pain killers. The consumer will find much entertaining reading, including such chapters as "Your Hangover and How Not to Have One." The work, which is intended primarily for the lay reader, admirably fulfills its purpose.

A History of Medicine in the State of New York and the County of Monroe. By Florence A. Cooksley, B.A. M.A. Librarian, Rochester Academy of Medicine. Reprint from New York State Journal of Medicine 1936. Cloth. Pp 63. Rochester, N.Y.: Rochester Academy of Medicine [n.d.].

Although not a member of the medical profession, the author has acquired a real sympathy and understanding of medical men and their problems through her contact with medical writings and men in her professional work. After a general discussion of medical schools and societies in America, especially those in the state of New York, she devotes about half of her writing to Rochester and Monroe County. Her familiarity with local records has enabled her to write intelligently of the progress of local medicine and of local medical societies. She has graphically related the story of the early struggles and discouragements in efforts to secure a permanent home for a scientific society, free from political affiliation, built about a medical library, and furnishing a center for all medical activities and a place for the meetings of all local medical societies. This was finally accomplished in the present Rochester Academy of Medicine. The experience of Rochester is like that of many cities and should serve to encourage those who elsewhere are still hoping for similar achievements.

Atlas of Congenital Cardiac Disease. By Maude E. Abbott, B.A. M.D. F.R.C.P. Assistant Professor of Medical Research, McGill University, Montreal, Canada. Cloth. Price \$5.50. Pp 62 with 26 plates embodying over 200 illustrations. New York: American Heart Association 1936.

Beginning with an excellent plate showing five great scientists who have made fundamental contributions to our knowledge of congenital heart disease, Dr. Maude Abbott has collected in an atlas a series of plates showing the development of the heart, a classification of cardiac defects, anomalies, pathologic specimens, congenital disturbances, valvular difficulties, dextrocardia and many similar congenital complaints. The book is beautifully printed and excellently indexed and a necessary source book for every practitioner concerned with heart disease.

Encyclopedia of Sexual Knowledge. By A. Costler, M.D. A. Willy, M.D. and others under the general editorship of Norman Haire, Ch.M. M.B. Cloth. Price. Popular edition \$3. Pp 567. New York: Eugenics Publishing Company 1934.

This collection of essays by a variety of writers on modern sexual subjects is obviously written to appeal to a public audience, although a note states that it is positively restricted to physicians, lawyers, ministers, educators and social workers. Almost anybody can qualify under those categories. The book contains a great deal that is not well established in the physiology of sex. The book answers most of the questions that would occur to any one in relationship to sexual activities and also discusses a great many things that would not ordinarily occur to every one.

Aids to Diagnosis and Treatment of Diseases of Children. By F. M. B. Allen, M.D. M.R.C.P. Lecturer in Infant Hygiene and Diseases of Children, Queen's University Belfast. Seventh edition. Cloth. Price \$1.50. Pp 329. London: Baillière Tindall & Cox; Baltimore: William Wood & Co 1937.

This little book is remarkable for its completeness. The essentially pediatric subjects are covered in considerable detail. Discussions of infant feeding, enuresis and rheumatic fever, for instance, are quite complete. As evidence of its completeness, cevitic acid is suggested for scurvy, and in Hirschsprung's disease the author states that sympathetic ramsection has been successfully performed. The consideration of blood diseases is rather superficial. There is an appendix with methods of preparing foods, prescriptions used, and incubation periods of various acute infectious diseases. There are also various tables. This little book gives considerable accurate information for the money and is easily read.

Der Blutdruck des Menschen. Von Dr. med. Eschl. Kylin, Direktor der Medizin. Abteilung des Centrallasarettet, Jönköping/Schweden. Paper. Price 24 marks. Pp 322 with 22 illustrations. Dresden & Leipzig: Theodor Steinkopff 1937.

This monograph is a thorough review of the problems of abnormal arterial tension. The work is scholarly and well planned and contains a large and well selected European bibliography. Although the views of Kylin are not all generally accepted, the monograph is worthy of serious study by those specially interested in hypertensive arterial disease. It is not adapted to general medical or student consumption.

Dust of Our Time By H. Ameroy Hartwell. Cloth Pp 82 with one illustration by Fabion Zaccane Weehawken N. J. The Author 1936

The poems in this collection have the distinct feeling and tone that physicians and biologists invariably give to their poetical contributions, yet Dr. Hartwell's poems are not primarily medical. He is concerned equally with beauty in every field and he is able to reflect this in his writings. He is inclined primarily to the sonnet form, yet there is no limit to his variations.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts Delegation of Legislative Authority to Dental Schools and to Examining Board.—The dental practice act of Florida requires, among other things, that the examination of an applicant for a license must include "such subjects as are taught in accredited dental schools, and any other subjects which in the discretion of the Board are necessary." Pridgen, arrested for practicing dentistry without a license, petitioned the Supreme Court of Florida for a writ of habeas corpus, contending that this requirement was unconstitutional in that it constituted an invalid delegation of legislative authority to accredited dental schools and to the board of dental examiners.

The requirement that the examination "shall include such subjects as are taught in accredited dental schools," said the court, should be construed in connection with another provision of the dental practice act which requires that an applicant for examination shall file "his diploma or certificate of graduation from an accredited dental college as defined by the National Association of Dental Examiners." The latter requirement was held valid, as against the contention that it was an unlawful delegation of legislative authority, in *Spencer v. Hunt*, 109 Fla. 248, 147 So. 282. The two requirements taken together sufficiently define, the court thought, what is meant by the term "accredited dental schools." The requirement "against which counsel for petitioner leveled their heaviest artillery" in the present case, namely, the inclusion of "such subjects as are taught in accredited dental schools," was neither unreasonable nor arbitrary, the court continued, if fairly and justly administered by the board in keeping with the plain language of the statute. There was no showing here of any discrimination or wrongful conduct on the part of the board, and the presumption is that the board did its duty. It might have been a desirable safeguard against possible discrimination if the act had required the board of dental examiners to adopt a general rule or regulation specifying the subjects on which all applicants would be examined. In such case, the reasonableness and validity of such a general rule could easily be reviewed by the courts. The court, however, was by no means convinced that the requirement of the act under consideration constituted a delegation of legislative power, or that it was so vague and indefinite in its meaning as to deny to an applicant due process of law or the equal protection of the laws as guaranteed by the federal constitution.

But, said the court, the act further purported to authorize the board to examine applicants in "any other subjects which in the discretion of the Board are necessary." While the legislature may expressly authorize designated officials within definite limitations to provide rules and regulations for the complete operation and enforcement of the law within its express general purpose, it may not delegate the power to enact a law, or to declare what the law shall be, or to exercise an unrestricted discretion in applying the law. Under this provision, the board would be authorized to add any other subjects to those taught in accredited dental schools which in its discretion it might think necessary, however unrelated such additional subjects might be to the science of dentistry or dental surgery, and it might change these added subjects with each examination. This would open the door to rank discrimination as

between applicants without any means of redress. This provision, in the opinion of the court, not only constituted an undefined delegation of legislative power but would easily operate to deny the equal protection of the laws. It also falls within the condemnation of the rule against the delegation of legislative power by vague and general provisions. The objectionable clause, being unconstitutional, may be regarded as stricken from the act, leaving the remainder of the requirement in full force and effect. The petition did not show, the court said, whether the elimination of this objectionable clause from the act would have had any effect on Pridgen's case. The examination might have been confined to questions on such subjects as are taught in accredited dental schools, and hence within the valid requirements of the act.

On a rehearing, the court said that the failure of the act to fix any grade or percentage that an applicant must make did not invalidate the act. The board of examiners was authorized to adopt rules, and, in the absence of evidence to the contrary, it will be presumed that it has done so. If arbitrary or unreasonable rules with respect to passing grades have been adopted, there was no evidence of it. The act contemplates that only fair and reasonable rules shall be adopted, and in the absence of a showing to the contrary it will be presumed that the board members have done their duty. The court accordingly adhered to its original opinion, remanding Pridgen to the custody of the sheriff.—*Pridgen v. Sweat, Sheriff (Fla.)*, 170 So. 653.

Patents Evidence Insufficient to Show Anticipation of Hart Copper-Iron Patent for Treatment of Anemia.—In 1932 a patent was granted to E. B. Hart, professor of agricultural chemistry, University of Wisconsin, covering a combination of copper salts and the salts of iron, to be used for the treatment of anemia. Hart assigned his patent to the Wisconsin Alumni Research Foundation. The Foundation brought suit in the district court of the United States for the Western District of Missouri against George A. Breon & Company, alleging infringement of the patent. The defendant contended that Hart's patent was invalid inasmuch as the combination covered by it had been in use in the United States and had been described in publications in foreign countries before application was made for the patent. The district court dismissed the suit, and the Foundation appealed to the United States circuit court of appeals, eighth circuit.

The theory of the Hart patent, said the circuit court of appeals, and of the infringing product of the defendant, is that, when iron salts and copper salts are fed into the alimentary canal, the iron finds its way into the hemoglobin of the blood, that the copper, although it does not become part of the blood, "actuates" the iron, and that unless a salt of iron is combined and administered with a salt of copper, the iron salt is not effective. The sole question to be determined, said the court, is whether or not the invention described in the Hart patent had been anticipated. The validity of a patent is presumed, and that presumption can be overcome only by clear and satisfactory proof. Where foreign publications are relied on as vague and general representations will not support a defense, knowledge derivable from such publications must be sufficient to enable persons skilled in the art or science to understand the nature and operation of the supposed invention and to carry it into practical use without assistance from the patent alleged to have been anticipated.

The first of the publications offered in evidence by the defendant to prove that the Hart copper-iron patent had been anticipated was a catalogue issued in 1924 by the Haver-Glover Laboratories, manufacturers of veterinary medicinal preparations. The catalogue contained various formulas including copper sulfate, iron sulfate, and other ingredients for the treatment of intestinal parasitism in sheep and swine, of coughs in horses and cattle, of heaves in horses, of fowl cholera and of white diarrhea in chicks, but nowhere in it was anemia mentioned. A veterinarian testified for the defendant that all the diseases named were associated with anemia. The facts taken together, however, did not, in the opinion of the court, show that the catalogue in evidence disclosed the invention covered by the patent here under consideration. The burden was on the defendant to prove that the combination that he claimed to be

anticipatory of Hart's patent produced the same cure as that for which Hart's patented remedy was alleged to be a specific, not to show merely that that combination was a proper treatment for some other disease

An article published in Italian in 1862 by Dr L. Mendini, on a "Remedy for Amenorrhoea," was offered in evidence by the defendant. This article, said the court, clearly does not teach with that certainty required by law to invalidate a patent, that a combination of iron and copper is a cure for anemia. It does not appear from that article that scientists or doctors of medicine learned from it the virtues of such a combination for that purpose. It does not disclose even whether a formula containing iron was or was not used by the author. On the other hand, the author, in the judgment of the court, attributed the curative effect of the combination to copper alone, for he says that he "had many times awaited in vain when using pharmaceutical iron sulfate." Liegeois, in reviewing the works of Mendini in 1901, interpreted them to mean that Mendini's cures of chlorosis were due solely to the use of copper and not of iron.

A thesis by Albert Gonnet, entitled "Contribution to the Study of Copper and Its Compounds in Toxicology and Therapeutics," was offered in evidence. It discussed the therapeutic value of the copper sulfate found in the waters of various mineral springs in Europe. Gonnet clearly said that copper salts are a cure for anemia, as well as that iron constitutes such a cure, but he did not state that copper and iron must be combined to effect a cure. Such an inference from his writings, in the judgment of the court, was not plausible.

The defendant introduced in evidence also the translation of an article by Liegeois, published in 1900, entitled "Iron, Arsenic or Copper in Chlorosis." Liegeois, the defendant claimed taught in this article the principle on which the patent under consideration was based. He discussed the beneficial effect of the waters of the springs of Arceaux, containing copper sulfate, as a treatment for chlorosis, and apparently for the purpose of showing that the good results were not due to copper alone, he said that carbonate of iron and of manganese, arsenates, and chloride of sodium in the water had to be taken into account. Liegeois' article, said the court, does not teach the formula of the Hart patent. It attempts to prove that copper sulfate alone is a remedy for one form of anemia. It admits that the proof of its efficacy is not complete because of the presence in the spring water of several other substances, including iron, but Liegeois does not claim that copper must be combined with any of these substances in order to effect a cure.

A series of publications by a group of Italian scientists, offered in evidence, recognized that iron is an element of hemoglobin, and the authors sought to prove that other heavy metals could be substituted for iron. The authors' explanation of their difficulty in segregating copper from iron and other substances in the course of their experiments, did not, however, in the judgment of the court, teach that there was efficacy in any combination of the metals referred to, which was the essence of the Hart patent under consideration.

Expert witnesses testified that some of the publications introduced in evidence disclosed the use of combined iron and copper salts to cure anemia. The circuit court of appeals was persuaded, however, that the testimony of these witnesses was inconsistent with the plain statements of the authors of the publications that they undertook to interpret. In the opinion of the court it never occurred to the authors whose publications had been produced in evidence that the remedy for which they were searching, namely, a remedy to increase the hemoglobin content of the blood was to be found in some combination of inorganic iron and copper in definite proportions. The publications produced in evidence were clear, and in the judgment of the court, the assistance of experts to understand them was wholly unnecessary. They failed to disclose any anticipation of a combination such as that under consideration in such full, clear, and exact terms as to enable a person skilled in the art to produce and use it, without the necessity of experimentation. No scientist in all the years since these publications first appeared learned from them the teachings of the patent from the publications in evidence. Hart, the inventor in the judgment of the court discovered the formula embodied in his patent through independent and original investigations.

The circuit court of appeals held that the Hart copper iron patent had not been anticipated and that it was valid. The judgment of the trial court dismissing the suit was reversed. The case was remanded to the trial court for such further proceedings as were indicated.—*Wisconsin Alumni Research Foundation v. George A. Breon & Co., Inc.*, 85 F (2d) 166

Right of Private Hospital to Recover for Medical and Surgical Services—The defendant's wife was an inmate of the plaintiff's private hospital, where she was treated by a staff physician and by a surgeon not a member of the staff, whose employment was authorized by her. The hospital sued to recover the value of services performed, classified by the court as hospital services, medical and surgical services and nurse's services. The only matters in controversy were the plaintiff's right to recover (1) for the services rendered by the nurse and (2) for the services rendered by the physicians. In the absence of evidence to show that the nurse was not one of the regular staff of nurses employed under the direction of the administrative staff of the hospital, the court held that the plaintiff might properly recover the value of her services. A comprehensive survey of the relationship existing between hospital, physician and patient, however, said the court, compelled it to adopt the view that a hospital, rather than practicing medicine per se, is a place where medicine is practiced by physicians. The cases relegate a hospital to the role of a specialized hotel where the sick or infirm in body or mind may be treated by physicians expressly or impliedly employed by them. In the present case no impediment existed to a suit by the physicians who treated the defendant's wife. To allow recovery by the hospital for medical services would conceivably lay the foundation for two recoveries for the same acts, in the absence of a legal assignment to the plaintiff of the physicians' claim for compensation for their services. In the absence of any such assignment, the municipal court of the City of New York, Borough of Queens, first district, dismissed the hospital's claim for compensation for physicians' services.—*Daly's Astoria Sanatorium, Inc., v. Blair* (N Y), 291 N Y S 1006

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Rheumatic Heart Disease in Philadelphia Children—Cahan believes that about 1 per cent of the 350,000 children in the public and parochial schools of Philadelphia have some form of heart disease. Eleven public school physicians reviewed the medical record cards of 33,293 pupils enrolled in one school district. Of the 863 pupils listed for observation of their hearts by these physicians, 391 were considered worthy of study. The study has been made with the aid of an adequate history of juvenile rheumatic infection, and physical examinations for the detection of circulatory diseases. Examination was made twice at an interval of about one year, and in many cases a third examination was made in 1936. For recording moderate cardiac hypertrophy, a new landmark (preaxillary line) on the anterior wall of the chest is being suggested. It is an imaginary line on the front of each side of the chest, drawn vertically downward, midway between the midclavicular and anterior axillary lines, and parallel to them. Unlike the parasternal line which is similarly drawn from the medial half of the clavicle, the preaxillary line does not take origin from the outer half of the clavicle. The parents, the family physician, the pediatrician, the cardiologist and the hospital clinics form the main agencies for protecting children against the spread and aggravation of juvenile rheumatic heart disease. However, it is suggested that the school physician and nurse and the school principal should also be enrolled in a permanent campaign to assist in the detection and amelioration of rheumatic heart disease in children. The school years are a very important period in the child's physical life and development and have greater potentialities for the good or evil of a child with heart disease than of a healthy pupil. Their combined efforts can guide many of these unfortunate children more safely through the early educational years, prepare more wisely for a suitable vocation and at the same time choose safe avocations. It is possible that such wholehearted cooperation may reverse the tide and cause a decrease in the incidence of rheumatic heart disease not only in children but in adults.

Severe Bone Marrow Depression Following Arsphenamine—A study of the reports in the literature of blood dyscrasias caused by arsphenamine and of their two patients followed by Lieberman and Weiss from about June 1933 has confirmed their belief that most cases may best be considered early or late instances of the same toxic process which in its

severest form causes complete aplasia of the bone marrow. The two cases of complete bone marrow depression occurred several months after the administration of arsphenamine. An individual constitutional susceptibility of the bone marrow to the toxic agent may explain the occurrence of this relatively rare disease. In mode of onset blood pictures and clinical characteristics such cases resemble those due to chronic benzene poisoning. Although there is no definite proof, it is likely that the benzene ring into which the arsenic is substituted in arsphenamine is responsible for the blood dyscrasias, and not the arsenic. A study of bone marrow depression in chronic benzene poisoning and after arsphenamine administration indicates that the toxin most often shows an early affinity for the leukoblastic tissue in the bone marrow. Thus the early, easily reversible action of arsphenamine on the hematopoietic system is most often a reduction in the white blood cells, particularly the polymorphonuclears. Clinically this is expressed as a neutropenia associated with signs of lowered resistance—weakness, persistent colds, numerous smaller infections and the like. If this early neutropenic stage is recognized and the administration of arsphenamine stopped, the patient may be spared the later and frequently irreversible effects on the bone marrow of the accumulating arsphenamine (benzene). Reduction in the number and quality of the platelets with consequent bleeding from the mucous membranes of the nose, mouth and gastrointestinal tract is more likely to be a later than an early effect. The bleeding alone explains the marked secondary anemia that finally occurs in most cases, although a direct depression of the erythroblastic tissues may be the cause of the erythrocytopenia in some. If puncture reveals a bone marrow that is not aplastic, blood transfusions persisted in for many weeks may tide the patient over the period of temporary marrow inactivity and lead to permanent recovery, as in the two cases reported. If a true aplasia of the bone marrow has already resulted, the outlook is practically hopeless. The prognostic importance of bone marrow puncture in this connection cannot be overemphasized. Persistently repeated transfusions offer the only hope at this late stage of the disease.

Friedlander Bacillus Infections—Baehr and his colleagues report 198 instances of Friedlander bacillus infections which indicate that the organism is predominantly associated with abdominal infections, especially suppurations due to perforations of the appendix and colon, and next most frequently with excretory infections of the biliary and the urinary tract. In this respect it conforms pathogenically with *Bacillus coli* and other gram negative bacilli of the intestinal flora. In comparison with the frequency of Friedländer infections of the abdominal viscera, infections of the respiratory tract with this organism are relatively uncommon. It is therefore recommended that the terms *Bacillus pneumoniae* and *Pneumobacillus* be abandoned because they have served to perpetuate a wrong conception of the essential role of the bacillus of Friedländer in infections, and that the bacteriologic designation *Klebsiella pneumoniae* be changed to *Klebsiella friedländeri*. In the 198 infections there were only two cases of pneumonia in which the clinical and bacteriologic evidence during life left no doubt that the Friedländer bacillus was the primary cause of the pulmonary infection. These were the only two proved cases observed at the Mount Sinai Hospital, New York, during a period of thirty-six years. In seven other cases of lobar or bronchopneumonia the Friedländer bacillus was recovered from the sputum or lung during life in association with pneumococci or streptococci.

Vitamin C and Infection—Faulkner and Taylor sought evidence with regard to the effect of infection on the vitamin C metabolism by estimating the blood ascorbic acid in a large group of hospital patients and controls, and by "balance" experiments in a few patients with infections. They observed that the serum ascorbic acid levels in patients with infections are usually well below the values seen in normal persons and often reach figures encountered in manifest clinical scurvy. The amount of vitamin C in the diet necessary to bring the serum level and the urinary output to normal values in the presence of infection is far greater than the normal requirements. The effect of rheumatic fever on the vitamin C metabolism appears to be the same as that of other infectious diseases.

The Glomus Tumor—Slepjan cites two cases of glomus tumor which illustrate the type of neurovascular tumor that has recently attracted so much attention. In case 1 four years has elapsed since the tumor was removed. Although there is not sufficient clinical evidence to suggest a recurrence, deep pressure over the scar causes severe radiating pain up and down the anterior aspect of the leg. Recently an instance of a non-metastasizing malignant tumor of the small pelvis derived from the glomus coccygeum was reported by Kufner, who expressed the opinion that, since the glomus coccygeum is a homologue of the normal glomus, all tumors arising from it are glomus tumors. The author has been unable to find other reports of malignant changes. The history of a benign, slow growing, painful subcutaneous nodule with or without associated vasomotor changes of the extremities should suggest a glomus tumor. The histologic picture will readily confirm the diagnosis. Simple excision of the tumor leads to immediate alleviation of the pain.

- Intradural Abscess Complicating Acute Mastoiditis with Subperiosteal Abscess in an Infant Report of Case G W Olson Fresno Calif—p 693

Pathways in Infections of the Mastoid—In contrast to the general belief that the common source of infection of the mastoid is through the natural anatomic atria—the eustachian tube tympanum antrum and mastoid cells—Hadjopoulos and Bell give evidence to support the less accepted theory that the

major and more important sources of infection of the mastoid are the blood and lymph channels of the adjacent mucosa. A means of demonstrating streptococci in mastoid tissues failed to show streptococci diffusely disseminated in such tissues. On the contrary, they encountered them strictly localized in certain channels in the tissues, of which some were definitely venous, others lymphatic and still others indefinite as to origin but definite in outline.

Management of Infections of the Blood Stream from Mastoiditis—Fenton submits certain points in clinical management of two recent cases of otitic septicemia. The first of these boys had so violent an invasion of the blood stream within forty-eight hours that six large transfusions over a course of six weeks were required to bring his temperature to normal and to secure a negative blood culture. The second lad, whose tremendous drop in resistance was evidenced by his lack of fever and leukocytic response, had a complete occlusion of one jugular vein, probably at the bulb, yet he required only five small transfusions and was out of the hospital in less than four weeks. In neither case was there evidence of any inflammatory process in the mastoid portion of the sigmoid sinus or in the exposed jugular vein when tied. Yet the entire mastoid process in each child was filled with thin seropus and black clots. The bony trabeculae were still hard. It seemed wise to isolate any possible obstruction or mural clot in the region of the bulb by destroying the jugular vein below as well as the sigmoid sinus in the mastoid. As much time as possible was saved in both operations by the use of ethylene anesthesia and by having a second surgical team attend to the jugular ligation the instant the mastoid wound was packed and sutured. There was no roentgenographic preoperative evidence of anomalies of the sinus to explain the closed left jugular vein in the second case. Routine blood typing of all patients with involvement of the mastoid should be done, especially children in whom there seems any possibility of sinus involvement. Thus, it is known whether a supporting blood transfusion should precede an operation or/and follow it by as many others as may be needed. The main point in the treatment of aural disease in cases in which blood cultures are positive or in which one suspects that such cultures may be obtained by proper technic seems to be swift, shockless and complete operation, preceded or accompanied by blood transfusions. Blood culture does not fail as often if made just before an expected rise in temperature, often at the beginning of a chill.

Prolonged Coagulation Time Subsequent to Anaphylactic Shock—According to Eagle and his associates the retarded coagulation observed in six rabbits and eleven dogs immediately after anaphylactic shock was regularly associated with the presence of increased amounts of antithrombin in the blood. The increased antithrombin activity was as much as a hundred times the normal level. The fibrinogen content of the plasma was not significantly affected. There is reason to believe that even the plasmas completely noncoagulable by calcium and tissue extract nevertheless contained sufficient prothrombin to effect coagulation, and although the platelet count was usually decreased after anaphylactic shock the

amount remaining would ordinarily have sufficed to cause coagulation within approximately normal time limits. The increased antithrombic activity of the blood after anaphylactic shock is apparently the primary cause of the observed retardation of coagulation.

Serum Phosphatase in Diseases of Bone—Mitchell and Crawford review the literature pertaining to the clinical application of serum phosphatase to bone disease and present the results of their investigations. They find that, in general, there is an increase in serum phosphatase activity accompanying the formation of unusual amounts of new or of abnormal bone. There appears to be little or no increase associated with the purely destructive lesion of bone. Determinations of serum phosphatase are an important aid in the diagnosis and differential diagnosis of Paget's disease, osteitis fibrosa cystica and tumors of bone. The level of serum phosphatase activity cannot be used as an index of healing or of the ability of a fracture to heal. No significant changes in serum phosphatase activity were noted in cases of bone and joint tuberculosis and of osteomyelitis. Serial phosphatase determinations are suggested as a criterion of effective therapy in Paget's disease, hyperparathyroidism, osteoblastic osteogenic sarcoma and rickets.

Joint Changes from Patellar Displacement—Bennett and Bauer endeavored to determine the effects of patellar displacement in knee joints (in rabbits) which had not been opened surgically or traumatized in any other manner, and to compare the changes produced with those found in human knee joints with displaced patellas. From their observations, it is apparent that the chief characteristics of degenerative joint disease—degeneration of articular cartilage, condensation of subchondral bone and marginal lipping—do occur soon after displacement of the patella. That similar intra-articular changes develop at an early age in the human knee joint as a result of patellar displacement is well illustrated by a case that

they report. Patellar displacement is of itself adequate cause for degenerative and hypertrophic changes in cartilage, similar to those of degenerative joint disease. The undue pressure and friction of the experimentally displaced patellas resulted in rapid loss of the underlying articular cartilage with subsequent eburnation of the subchondral bone. The absence of normal patellar apposition and, in consequence, of lubrication of the nonarticulating surfaces with synovial fluid was responsible for articular cartilage degeneration and atrophy. Proliferation of the connective tissue at the perichondrial margins of the articular surfaces led to well defined marginal overgrowth. This marginal overgrowth was sufficiently marked to form a new patellar articulating surface on the medial side of the femur. The repeated stretching of the synovial membrane at its insertion, coincident with full extension, would seem adequate stimulus to cause the vascular, undifferentiated, perichondrial connective tissue to proliferate sufficiently to result ultimately in marginal lipping. Such marginal proliferation occurs to some degree in all joints with increasing age and long continued use but develops much more rapidly in joints with anatomic derangements such as patellar displacement. The clinical and pathologic observations from the patient with bilateral displacement of the patella were identical with those of degenerative joint disease. These studies emphasize the importance of early corrective measures in patients with a displaced patella if irreparable joint damage is to be prevented.

Lymphatic Leukemia with Pertussis—Levy and his associates report a case of lymphatic leukemia with pertussis and emphasize the absence of similar case reports. The difficulties encountered in differentiating lymphocytic reactions in acute lymphatic leukemia and pertussis are discussed. Attention is called to the confusion that may arise in differentiating between a remission of a lymphatic leukemia and a case of convalescent whooping cough. Hyperleukocytosis in pertussis should be followed by repeated blood counts so that latent leukemias may be detected.

"Rapid" Micro-Hinton Test for Syphilis—Davies developed a micro-Hinton and a capillary Hinton flocculation test (*J Lab & Clin Med* 22 952 [June] 1937) which employ

small amounts of serum. Since February 1935 more than 500 blood specimens, obtained in most instances in a routine way by skin puncture from patients at the Infants' and Children's Hospitals, have been examined by either the micro-Hinton or the capillary Hinton method or both. It has been possible to check the accuracy of 464 of these tests against the clinical diagnoses and the results of other tests. The micro-Hinton and the capillary Hinton tests were found to be 91.9 per cent sensitive and 100 per cent specific. The control Hinton test, performed on the same specimens in another laboratory, was 88.6 per cent sensitive and 100 per cent specific. The micro-Hinton and the capillary Hinton tests share the general advantages of the regular Hinton flocculation test in accuracy, ease of performance, economy and stability of the glycerinated antigen or "indicator" employed. No apparent loss of sensitivity has followed the shortening of the incubation period to one-half hour from sixteen hours. Of 238 "rapid" micro-Hinton and capillary Hinton tests, all but three agreed with the regular Hinton tests. One micro-Hinton test was positive when the Hinton test was doubtful, one capillary Hinton test was negative when the Hinton test was doubtful, and one capillary Hinton test was positive when the regular Hinton test was negative.

Hemophilia in Negroes—Pachman has seen three Negro hemophilic patients, two of whom have a definite family history and a genealogy which is fairly typical. In the third case the diagnosis may be questioned, but the history and the x-ray studies are typical of hemophilia. Blood coagulant extract from the placenta was tried in two cases, with apparent good results in one case. Theelin therapy was followed by improvement in one case.

Diagnosis, Treatment and Prognosis in Tuberculous Tracheobronchitis. P C Samson. Ann Arbor Mich.—p 561.

End Results of Thoracoplasty—Freedlander and Wolpaw compare the results in 153 patients to whom thoracoplasty was recommended, eighty-five of these patients accepted operation and fifty-eight refused. From one to four years later 66 per cent of the thoracoplasty group were closed or improved, in contrast to 17 per cent of the control group. On the other hand while 21 per cent of the thoracoplasty group were worse or dead, this was the fate of 61 per cent of the control group. Therefore, in the series, thoracoplasty increased by four times the chance of therapeutic improvement and decreased by two thirds the possibility of becoming worse. In the slipping chronic group thoracoplasty increased by seven times the possibility of therapeutic improvement and decreased by slightly less than two thirds the possibility of becoming worse. In the good chronic group thoracoplasty increased by three times the chance of therapeutic improvement and decreased by slightly more than two thirds the possibility of becoming worse. To delay operation in the good chronic case in the hope of spontaneous recovery is unjustifiable. A study of ten patients whose operation was delayed from one to three years after it was first advised contributes further evidence that procrastination is hazardous.

Closed and Open Intrapleural Pneumonolysis—Anderson and Alexander used the closed intrapleural pneumonolysis in 111 patients between 1927 and 1934. The operation was performed in the 111 cases an average of 8.6 months after the induction of pneumothorax. Open intrapleural pneumonolysis was used in twenty-nine cases. Of the 111 and twenty-nine

patients, respectively, 20.7 and 20.7 per cent were arrested or apparently arrested, 14.4 and 3.4 per cent were quiescent, 42.3 and 55.1 were improved, 10 and 10.4 per cent were unimproved or worse and 12.6 and 10.4 per cent died. The authors conclude that closed intrapleural pneumonolysis is a highly valuable operation for certain carefully selected cases of inadequate pneumothorax that are unsuitable for treatment by phrenic paralysis. In well selected cases, closed pneumonolysis is decidedly preferable to thoracoplasty. In a considerable proportion of patients for whom closed pneumonolysis is technically possible, thoracoplasty is contraindicated because of too active lesions in the contralateral lung. Open intrapleural pneumonolysis is valuable for a small group of patients whose adhesions are too short or complex in arrangement for safe division by the closed method of pneumonolysis. An open operation may be used for certain cases of bilateral active tuberculosis for which a thoracoplasty would be definitely contraindicated. Open intrapleural pneumonolysis should be reserved for those patients in whom phrenic paralysis, if indicated, and closed intrapleural pneumonolysis have already been tried, and in whom thoracoplasty is contraindicated and to whom the open operation offers the only chance of recovery.

Absorbable Sutures Made from Fetal Membranes—

Johnson believes that by the use of properly prepared and

preserved membranous patches, made from human amniotic and

bovine allantoic and amniotic membranes, a substantial con-

tribution can be made to the successful handling or rather

prevention of the formation of postoperative adhesions. A care-

ful operative technic in the application of the patch is essential

if good results are to be obtained. Gross and microscopic

study of the tissues involved shows that this new technic is

safe and effective in the experimental animal. The use of

insulating patches may prove especially applicable to surgery

of the peritoneal cavity, tendons, nerves, blood vessels and

joints.

Roentgen Signs of Sequels of Head Injuries—In his experience, Travers has found encephalography of definite value in the study of posttraumatic sequels, and particularly in the differential diagnosis of subdural hematoma. In a recent series of fourteen cases with posttraumatic sequels of head injuries there were four cases of subdural hematoma (confirmed by operation). The encephalographic studies in these cases revealed a marked shift of the ventricular system to the side opposite the lesion, with compression and deformity of the ventricle on the side of the lesion or (in one instance) a failure to demonstrate this ventricle at all. Failure of the subarachnoid space to fill on the side of the lesion was also discerned in another instance. In only one case was a diagnosis of subdural hematoma made preoperatively which could not be confirmed at operation. In the remaining nine cases there was roentgenologic evidence of brain atrophy. In three cases there was enlargement of both lateral ventricles, and in two of these a corresponding dilatation of the third ventricle. In all three cases the cerebral sulci were coarse, an indication of cortical atrophy, and in one case the basal cisterns were enlarged showing atrophy of the adjacent structures. In the latter case one of the lateral ventricles was slightly larger than the other. In five of these nine cases, one lateral ventricle was dilated and the sulci were coarse, in one case porencephaly was noted. In these five cases there was almost complete relief of symptoms following encephalography. Any displacement of the ventricle in these cases of cortical atrophy was toward the site of the lesion, owing to cortical fibrosis. In one case—in which the exact diagnosis was doubtful—there was air in the subdural space but no evidence of brain atrophy.

Unusual Types of Intracranial Tumors—Pilcher states that the majority of intracranial tumors fall into three great groups: the gliomas, arising from the brain itself, the fibroblastomas, arising from the covering membranes of the brain and cranial nerves, and the tumors arising from the pituitary body and its related structures. There are, however, numerous unusual or rare types of tumor many of them benign, encapsulated and amenable to operative removal and cure. Five of these unusual cases are given. 1 The patient complained of right-sided headaches for ten years nocturnal convulsions for three years and tinnitus, dizziness and dreamy spells for three months. Removal of an osteoma of the right temporal bone resulted in recovery. 2 This patient had severe right-sided headaches for one year, following a blow on the head, and essential hypertension. Removal of a large intradural bony plaque on the right resulted in recovery. 3 Blindness and headache were present in this patient for two months after a

fall. A cystic tumor was located in the left occipital lobe and emptied by needle puncture. Then followed exploration and partial removal of a papilloma of the choroid plexus, reexploration and radical extirpation of the tumor. Two subsequent operations were necessary for removal of recurrent tumors in a period of fifteen months, followed by high voltage roentgen therapy. The patient is symptom free at present. 4 The fourth patient suffered from left-sided jacksonian convulsions for twelve years, left hemiparesis and hemihypesthesia. There was a history of treated syphilis. The removal of a cystic polar spongioblastoma resulted in complete recovery. 5 In the last patient, vision in the right eye had been failing for three years. There was a tiny spot of calcification in the right suprasellar region. Exploration revealed a large aneurysm of the right internal carotid. This was remedied, but subsequent spontaneous rupture of the aneurysm occurred, followed by death. The author believes that these cases serve as a pointed reminder that, whenever faced with obscure headache or visual disturbance, one should keep the possibility of brain tumor in mind.

- Medical Education as Factor in Solution of Present Problems W B Porter Richmond—p 158

Carcinoma of Sigmoid and Rectum—Graham is concerned with the two features which in his experience have most frequently given rise to confusion in the establishment of a diagnosis of carcinoma of the sigmoid or rectum: the passage of bright red blood at stool and persistent diarrhea, the so-called compensatory diarrhea which exists in the face of almost complete obstruction of the large intestine. There are no pathognomonic symptoms of cancer of the large intestine. For this reason early diagnosis can be accomplished in a high percentage of cases only if a thorough examination is made whenever a patient in the middle decades of life complains of symptoms referable to the gastro-intestinal tract (diarrhea, gradually increasing constipation, alternating constipation and diarrhea, bright red blood at stool or other symptoms even though vague in nature), especially if the symptoms persist over a period of two or more weeks. Failure to recognize the presence of bright blood at stool as the most constant sign, and often the only one, of cancer of the left half of the colon is of frequent occurrence. Of thirty-two consecutive cases of carcinoma of the rectosigmoid and rectum in which the author operated during the last three years, ten were treated for bleeding hemorrhoids prior to a diagnosis of cancer but during the period in which symptoms of the cancer were present. Yet in six a growth could be palpated with the finger, in three others it could be observed through the sigmoidoscope, and in the tenth case the defect caused by the lesion was readily visualized roentgenoscopically. Approximately 50 per cent of the thirty-two cases were originally diagnosed incorrectly: bleeding piles or colitis yet only two required diagnostic measures not available to every physician.

*Relation Between Systemic Lupus Erythematosus and Peculiar Form of Thrombocytopenic Purpura H Keil—p 221

Clinically Resembling Morphea with Tuberculous Background and Indeterminate Histology Suggestive of Necrobiosis Lipoidica Case D B S Bruce Jones—p 238

"Systemic" Lupus Erythematosus and Thrombocytopenic Purpura—Keil reports a case in which "superficial" lesions of lupus erythematosus, accompanied by constitutional symptoms, were succeeded or replaced by discoid atrophic patches scattered over the entire body. The lesions of the skin were healed or in the process of healing yet the clinical course was progressively downhill, ending in death ten months later from renal insufficiency. The lack of conformity between the course of the lesions of the skin and visceral phenomena (Keil) was shown clearly. Although the hematologic data supported the diagnosis of essential thrombopenia, an opinion apparently corroborated by the excellent result achieved by splenectomy, the peculiar subsequent course appeared to place the case in a distinct category. The association of systemic lupus erythematosus with the syndrome of thrombocytopenic purpura might at first be considered a coincidence were it not for the increasing number of cases in which the two disorders have been observed. The relation between systemic lupus erythematosus and a peculiar variety of thrombocytopenic purpura is given under the following headings: (1) relation of systemic lupus erythematosus to thrombopenia (Templeton) and to vascular disease affecting chiefly the smaller vessels of the body, mention being made of the formation of so-called hyaline thrombi, (2) "vascular nature" of a peculiar form of thrombocytopenic purpura, the distinctive feature being the generalized formation of 'hyaline thrombi' in smaller blood vessels, (3) association of systemic lupus erythematosus and thrombocytopenic purpura (when the former followed the latter at variable intervals of time, measured in months and when both occurred in close relation to each other). There is no clinical or physiologic basis for the belief that thrombopenia can be correlated with "extravascular bleeding" into the tissues or outside the body. The tendency to superimposed purpura in systemic lupus erythematosus, in most instances, is probably related to the capillary damage found in the disease. Other factors may also occasionally play a part—azotemia. The author has seen no instance in which diseased liver or superimposed bacteremia could be held responsible for the appearance of hemorrhagic manifestations. Gold therapy as a factor in the production or accentuation of purpuric phenomena in lupus erythematosus is discussed.

*Treatment of Trichomonas Vaginitis by Silver Picrate W A MacCall—p 1112

Treatment of Trichomonas Vaginitis by Silver Picrate—The full treatment as given by MacCall consisted of insufflation with 0.3 Gm. of silver picrate powder followed by daily dry swabbing and insertion of a pessary. Of the twenty-eight patients receiving the full treatment, on insufflation, Trichom-

onas vaginalis disappeared the next day from the secretions in twenty-six. In the two cases in which the trichomonads present on the second examination it was observed that numbers had decreased and that the organisms were sluggish in movement. The parasites were absent on the third examination. Of the twenty-eight cases fifteen (53.5 per cent) remained persistently negative, but in thirteen (46.4 per cent) a relapse or reinfection occurred. Of the relapses or reinfusions, five (38.4 per cent) occurred following a menstrual period. In all cases the local condition showed marked clinical improvement, the discharge becoming markedly less in amount, local inflammatory signs settling down, and such symptoms of irritation and soreness abating, in spite of the fact that in eleven of the cases there was coexisting gonococcal infection.

*Tumors of Base of the Brain Their Relation to Pathologic Sleep and Other Changes in Conscious State L B Cox—p 742

Tumors of Base of Brain—Cox presents cases of tumors unassociated with internal hydrocephalus, involving the midbrain and hypothalamic and thalamic regions, each accompanied by certain changes in the conscious state. These changes included such phenomena as drowsiness and hypersomnia, trance-like conditions, periods of apathy, catatonic states, alterations in disposition, disorientation for time and place, marked loss of memory and mental excitement. In certain cases the removal of the tumor resulted in recovery from the abnormal mental state. An attempt is made to explain the conditions of lessened consciousness as a disturbance of a sleep mechanism. A working hypothesis is formulated, based on the possible relation of sleep to an inhibitory process. The relation of conditions of exalted consciousness to the excitation or release from control of mechanisms for the expression of the emotions is discussed. It is indicated that the region of the brain stem, hypothalamus and basal ganglions may be of importance in the better understanding of the problems of insane conduct.

*Nonprogressive Solitary Arterial Hypertensions of Juveniles of Sympathetic Origin A Tourniaire—p 331
Lepra Bacillus Summary of Researches F L Acosta—p 335

Arterial Hypertensions of Juveniles, of Sympathetic Origin.—Among juvenile hypertension Tourniaire noticed a solitary, sympathetic type which has a favorable prognosis. The blood pressure in these young persons is mostly moderately increased and attains but rarely its maximal height. Exercise increases the pressure considerably, which in certain cases yields for a short while to sufficient rest. This hypertension remains latent and manifests itself in the form of functional disorders occasioned by physical strain, large intake of food and emotional disturbances. At times it is accompanied by a slight increase in the basal metabolism, but it is never the cause of a left ventricular hypertrophy. It is quite similar to the high pressure reaction commonly observed in tachycardic neuroses except for the rhythm of its heart beats, which remains normal. The author believes that he is dealing with an essential cardiovascular hypersympathicotony originating, as it were, from functional disturbances in the vasomotor center, close to the hypothetic center which regulates basal metabolism. The pathogenesis is still obscure and it must be differentiated from other juvenile high blood pressure diseases. From the latter it may be distinguished by its all round benignity, as it does not under any circumstances develop into a hypertension cardiopathy. The treatment is directed toward the cardiac instability. The patient needs a readaptation to gradually higher strains, or, in severe cases, functional radiotherapy, according to Gravier and Gounet, may be resorted to.

*Hereditary Syndrome Characterized by Hypoplastic Patella Malformation of Radius and Hemiatrophy of the Thumb Nails R Montant and A Eggermann—p 770

Hereditary Syndrome.—Montant and Eggermann have noticed certain hereditary characteristics in the bony system and nails of certain families. Those peculiarities concern exclusively blonds of either sex with light blue eyes. No relation to malformation has been observed. It concerns primarily the joints of the knees and the elbows (mesodermal origin) as also the nails of both thumbs (ectodermal origin). The hypoplastic development of the patella brings characteristic changes in the flexion of the knee joint and peculiarities of gait. In very pronounced cases of small or deficient patellas those persons have difficulties in descending stairs or slopes. Humeral condyles are found hypoplastic, the head of the radius projects itself beneath instead of above the coronoid apophysis, and the bicipital tuberosity is directed downward. The changes in the nails of the thumb vary from simple striations to ungual atrophy or dystrophy, and certain authors made the observation that those changes often go hand in hand with some mental or somatic degenerations such as idiocy or short and rare growth of hair, which is often white. According to Aschner a pertinent pathologic factor (one dominant gene) is situated in the chromosome so closely to other genes that they are inherited as a unit. The inheritance of those traits is therefore simply dominant and regular.

*Therapeutic Extrapleural Pneumothorax E Hautefeuille and Dreyfus Le Foyer—p 859

Extrapleural Pneumothorax.—Hautefeuille and Dreyfus-Le Foyer direct attention to extrapleural pneumothorax, a new form of collapse therapy, which effects the collapse of pulmonary lesions by creating a surgical cavity between the thoracic wall and the parietal pleura and by filling this cavity with gas, as

is done in the case of intrapleural pneumothorax. After describing and illustrating the technic, which they employed for the extrapleural pneumothorax of the pulmonary apex, the authors stress the advantages of this method. Like the intrapleural pneumothorax, it has the advantage of being elective. It maintains the collapse of the subhilus region of the lung by means of an elastic and modifiable gas pressure. Moreover, it is less trying for the patient than other methods of collapse: it preserves the expectorating function and it limits its effect to the apex or the base. The authors state that their experiences with the extrapleural pneumothorax confirm the favorable results obtained by Graf and Schmidt, who were the first to employ this method. They point out that extrapleural pneumothorax is indicated in the presence of pulmonary adhesion not yet extensive enough to justify a thoracoplasty, in patients with uncertain resistance or in those in whom the lesions are incompletely stabilized and in those with an apicomediastinal cavity, when it is feared that costal resection may produce inadequate results. Extrapleural pneumothorax is indicated especially in cases in which the lesions are still new but far enough away from the cortex so that an intrapleural pneumothorax may be judged ineffective. In cases in which collapse is incomplete on account of apical adhesions, the combination of the two types of pneumothorax may effect the desired collapse. The authors reach the conclusion that extrapleural pneumothorax deserves the attention of phthisiologists.

*Cure of Urticaria Gigantea Perstans by Solution of Posterior Pituitary W Rosenberg-Schauss—p 583

Ganglioneurofibromatosis of Mesentery with Malignant Degeneration.—Jentzer and Fatzer say that, in his first publication on neurofibromatosis of the skin, Recklinghausen pointed out that such tumor formations may develop also on the internal organs, particularly the gastro-intestinal tract. After citing several reports from the literature and after pointing out that such tumors are referred to also as neurinomas or schwannomas, the authors give a detailed report of a case which they observed. The patient, a youth aged 17, was hospitalized with the diagnosis of ascites of obscure etiology. The patient stated that he had observed the development of a tumor in the abdomen for the past two or three years. There was a gradual increase in size, but no other disturbances. However, a thrust against the abdomen ten days before hospitalization had caused severe pain, and five days later the mother of the patient observed that his abdomen rapidly increased in size. On the basis of the clinical examination, the condition was diagnosed as mesenteric tumor, the malignant nature of which was deduced from the rapid course and from the appearance of the ascites. An operation was performed, but the patient died five days later. The microscopic examination of the surgical specimen revealed (1) a plexiform neuroma of the mesentery and (2) a plexiform ganglioneurofibroma of the intestinal wall, which originated in Meissner's plexus. Although the patient had no other sign of neurofibromatosis, he did have other disturbances in the nervous sphere. The authors emphasize that, particularly in young persons, connections with the nervous system should be searched for whenever mesenteric tumors exist.

Cure of Urticaria Gigantea Perstans with Solution of Posterior Pituitary.—Rosenberg-Schauss observed a severe case of urticaria gigantea perstans in a man, aged 30. The condition had existed for six years, and during the last two years the patient had undergone various treatments (medications, rays, diets) without avail. The author, having obtained favorable effects with solution of posterior pituitary in various dermatoses that were accompanied by acute or chronic edema, gave this patient an injection of 1 cc of a proprietary brand of solution of posterior pituitary. After nine days the efflorescences showed a decrease. A second injection was given, and

twelve days later some of the efflorescences had completely disappeared. A third injection resulted in complete cure. Later the patient was given three more injections. The author thinks that chronic urticarial dermatoses should be treated with solution of posterior pituitary whenever an angioneurosis predominates in the dermatosis.

Pachyderma and Pachyperiostosis of Extremities—

According to Gromo, pachyderma in association with pachyperiostosis of the long bones is rare. The condition develops in growing children with few symptoms (fatigue and dull pain in the extremities). When puberty is passed the disease evolves no more, but the abnormal thickness of the long bones and of the skin of the extremities, scalp and face does not regress. The skin is hard, elastic and seborrheic and the features of the face, feet and hands show various alterations. The fingers are hippocratic. The cause of the condition is not known but is believed to be endocrine disorder. The evolution is chronic and benign. Otophary, local and hypophyseal roentgen therapy and plastic surgery fail. Heliotherapy relieves the pain of the extremities. The author reports a case in a girl, aged 18. The condition was previously described by Tourniaire, but in his cases the pachydermal skin was pleated, whereas in the author's case it was plane.

Paraffin Embedding of Sputum in Diagnosis of Cancer of Lung—Mosto and Polak state that early in the development of cancer of the lung the sputum contains groups of tumoral cells by means of which a diagnosis of cancer of the organ can be made. The histologic examination of paraffin embedding of the sputum is of diagnostic value. The diagnostic interpretation depends on the experience of the one who makes the examination. The diagnosis is tissular rather than cytologic. It is made by the structural changes and loss of orientation and of polarity of cells in groups. The presence of horny substances in the sputum indicates the advisability of performing further clinical and histologic examinations. It is advisable to make the examinations in serial sections of the paraffin embedding. In the author's hands the method has given 68.5 per cent of positive results. In all cases the diagnosis was verified by the clinical evolution of the disease or by necropsy.

Acidified Milk with High Fat Content in Eczema—According to Traversaro acidified milk with high fat content in the diet of infants suffering from eczema is well tolerated. It improves the nutritional condition of the patients and has a favorable effect on the evolution of eczema. The results of the diet are satisfactory regardless of the weight (diminished, normal or increased) of the infants. No local treatments are necessary. Satisfactory results in four cases are reported by the author. The treatment is complementary or supplemental to breast or artificial feeding. The infant is given three or four times a day a bottle containing from 100 to 200 Gm of acidified milk with high fat content, 5 Gm of water and 5 or 10 Gm of sugar. The treatment is discontinued altogether at complete disappearance of eczema, which takes place soon during its administration.

Indication for and Technic of Extirpation of Semilunar Bone W. Nell—p. 619

Roentgenologic Examination in Rectal Cancer—After citing inspection, digital examination, rectoscopy and roentgen examination as the methods that are used in the diagnosis of rectal cancer, Irsigler gives his attention to the roentgen examination. He attempts to answer the question when a roentgen examination is necessary and when it is desirable and describes the results obtained with this method at his clinic. He does not agree with Fischer, who maintained that roentgenoscopy of the rectum is unnecessary, since digital examination and rectoscopy provide all the information that is needed, but points out that in some cases, particularly cancer of the so called high rectum (pelvic colon), neither digital examination nor rectoscopy will reveal the cancer. Moreover, even in cancers that are lower down, roentgenoscopy will provide information not obtainable by other examinations. In rectal cancers in which there is a possibility that the neoplasm has already attacked the bone, a roentgenogram of the sacrum should be made. Roentgenoscopy of the rectum itself should be done with the aid of a contrast medium. It should always be preceded by a careful digital examination and, in order to avoid disturbing fecal shadows, the rectum should be irrigated before the roentgenoscopy. The contrast medium is introduced slowly and screen observations are made while this is being done. If after discharge of the contrast medium only a thin wall covering remains, the intestine is slowly inflated and the gradual unfolding of the intestinal wall is carefully watched. The patient is turned and exposures are made in the left and right oblique and lateral positions. The rather frequent tumors of the anterior wall are observable only if the rays pass through from the front. On the basis of typical cases, the author explains some of the fundamental aspects of the rectal carcinoma, such as the valve closure, the malignant contour, the malignant outline, the carcinomatous filling defect and the carcinoma crater. He discusses the differentiation of disorders, which resemble rectal cancer (metastases in Douglas' pouch in gastric cancer, the rectal complications of inguinal lymphogranuloma or proctitis). He admits that roentgenoscopy frequently fails to aid in the differentiation and that serologic reactions, exploratory excisions and so on must decide the diagnosis in such cases.

Treatment of Traumatic Rupture of Symphysis—

According to Sommer, traumatic ruptures of the symphysis are comparatively rare, he reports four cases that were observed at his clinic. After citing the histories of the cases, he discusses the mechanism of this type of ruptures admitting that it has not been fully explained as yet. However he is inclined to accept Finsterer's suggestion that the position of the legs at the time of the accident may be of decisive significance. In discussing the treatment he cites various surgical measures, such as wire suture and implantation of a piece of bone but emphasizes that it is better if a surgical intervention can be avoided, for it involves considerable risk. He thinks that surgical treatment should be restricted to the cases in which the conservative measures do not produce the desired results. He says that the latter are quite effective, provided they are applied correctly. Reposition should be done, if necessary, under anesthesia. Fixation requires well fitting bandages of linen or adhesive tape, moreover, circular plaster of paris casts or other rigid bandages are likewise helpful. Three of the four reported cases were treated conservatively. In two of these cases the cure and final result was favorable. The third patient died suddenly, after two months of treatment as the result of a pulmonary embolism. The necropsy revealed that in this case too the conservative treatment of the ruptured symphysis had produced satisfactory results. The author admits, however, that in severe cases in which the separation is especially

wide, the force of a simple compression bandage is inadequate. In order to overcome this deficiency of the conservative method, he employed an apparatus that exerts a sufficiently strong concentric pressure and effects a good approximation of the pubic bones. He describes and illustrates this simple apparatus, which can readily be applied to the side frame of a hospital bed.

Significance of Vitamin B for Surgical Diseases—Lauber investigated the importance of vitamin B (riboflavin) in the treatment of acute infections, of wounds and of bone fractures. His studies were made on rats, mice and rabbits. The experiments demonstrated that riboflavin is absolutely necessary for the maintenance of the defense powers of the organism but that the riboflavin requirements are not increased during acute infections. The cure of wounds and bone regeneration likewise do not increase the need of the organism for riboflavin.

*Tumors Caused by Irradiation Experimentally Produced Bone Sarcoma H Hellner—p 980

Diagnosis of Dental Infection by Short Wave Provocation—Gutzeit and Kuchlin describe a method of application of short waves to the dental root, which permits the differentiation of infectious foci that cause systemic disorders or diseases in other organs from those which are localized and not connected with the circulatory system. In the presence of the first type of focus the sedimentation speed of the erythrocytes is noticeably accelerated from two to four hours after a provocative irradiation with short waves, whereas the irradiation of the second type of focus does not have such an effect. Such a differentiation of the active and the inactive foci had not been possible, for neither the clinical nor the roentgenologic examination of the teeth permits such a qualitative differentiation. The recognition of the active foci prevents the blind, radical removal of all suspected foci and thus overcomes the chief objection of the conservative physicians against the radical treatment of infectious foci. The possibility of identifying the offensive foci prevents unnecessary crippling of the dental apparatus. The electrodes used for the short wave irradiation of the dental roots are 2 by 3 cm in size. They are applied in such a manner that the one is on the palatine or the lingual side and the other one on the buccal side of the tooth. According to the statement of the patients, the short waves produced a pleasant feeling. Pains or burning sensations should not develop if the apparatus is intact. The authors describe their experiences with the test on healthy and diseased teeth.

Therapy of Idiopathic Trigeminal Neuralgia—Meyer says that in treating cases of phlebitis of the lower extremities he observed that some cases were refractory to the otherwise successful treatment according to Fischer's method. Since such cases of phlebitis frequently originate in a tonsillar infection, he gave his attention to the cervical veins, particularly the jugular veins, which Dietrich had found inflamed in many cases of acute tonsillitis. By examining the cervical veins for sensitivity to pressure the author was able to corroborate the suspected involvement of the cervical veins in a number of cases. He also observed that nearly all patients in whom a latent phlebitis of the cervical veins existed complained of neuralgia and headaches but that, after the venous infection

had been counteracted, neuralgia and headaches ceased. In treating latent phlebitis of the cervical veins, he took into account his experiences in purulent phlebitis of the leg. He had observed that bandages were contraindicated in such cases but that the application of leeches produced excellent results. Accordingly he applies three leeches on both sides of the neck, over the jugular vein. The bleeding should be continued for a considerable time (in one case it was carried on for ten hours). As the result of the loss of blood the patients may feel weak after the treatment, but since the neuralgic disorders disappear promptly, the patients do not object to this. In view of the lack of effective methods for the treatment of idiopathic trigeminal neuralgia, the author recommends a trial with the leech treatment in all cases of idiopathic trigeminal neuralgia in which the cervical veins are sensitive to pressure.

Tumors Caused by Irradiation—Hellner points out that the incidence of roentgen cancers has decreased in recent years, despite the wider application of roentgen rays. Nevertheless, three cases of chronic roentgen ulcers and five cases of roentgen cancers came up for observation at the surgical clinic of the University of Munster during recent years. The three roentgen ulcers and two of the cancers developed in cases in which eczema was treated by means of roentgen rays, two roentgen cancers appeared after irradiation of parasitic scycosis on the face and the other roentgen cancer developed in the shoulder region on the basis of numerous wart formations and of a roentgen dermatitis following irradiation of apparently tuberculous lymph nodes of the axilla. None of these five cases of roentgen cancer developed on the basis of a roentgen-irradiated lupus. The author considers it important to emphasize this, because a large number of roentgen cancers develop after irradiated cutaneous tuberculosis. The periods which elapsed between the irradiation and the recognition of the cancer were four, eleven, fourteen, eighteen and nineteen years, respectively. In the case in which the cancer developed after four years the first disorder, the eczema had existed for eleven years. The author is unable to make definite statements regarding the doses that caused the cancers in the five cases, but he says that they were large in all instances. Moreover, the irradiations were given frequently and in most of the cases not by one but by several physicians. After pointing out that irradiation with radium may produce radium cancer, the author gives his attention to the roentgen sarcoma. He surveys fifteen cases of roentgen sarcoma of the joints after tuberculosis which were reported in the literature and then gives a detailed description of one case of his own observation. In this case the sarcoma developed eleven years after irradiation of a tuberculosis of the wrist joint. Further the author reviews the experimental production of bone sarcomas and of sarcomas of the soft parts in animals by means of radium irradiation. He reaches the conclusion that in tuberculosis of the bones and joints and in other bone changes, the application of ray treatment requires extreme caution, particularly if the lesions are near the epiphyses.

Structure and Function of Corpus Luteum Produced by Estrogen E Klaffen—p 64
Examination of Surgical Preparations for Trichomonas M Rodcirt—p 99
*Pathogenicity of Trichomonas Vaginalis H Mohr—p 115

Uterine Tumors Originating in Wolffian Bodies—Limburg describes two rare forms of uterine tumors the histologic structure of which greatly resembles that of the epoophoron and of the wolffian duct. This structure makes probable their development from misplaced portions of the wolffian bodies. Both tumors consist chiefly of canalized, coiled, cylindric strands, the walls of which consist of an external circular a median longitudinal and an inconstant internal circular layer of spindle-shaped muscle or connective tissue cells, the lumens of which are lined with cubical epithelium, which usually appears in a single layer. In one of the two reported cases the connective tissue of the tumor underwent sarcomatous

degeneration and relapses and metastases developed. As regards their histogenesis, both of the reported cases are of the same type as the first one on record, a case of uterine adenomyoma originating in the wolffian bodies, which was described by Richard Meyer in 1903. The author was unable to find other reports of such cases in the literature.

Pathogenicity of Trichomonas Vaginalis—In reviewing the literature on the pathogenicity of *Trichomonas vaginalis*, Mohr points out that some investigators regard this parasite as harmless while others consider it pathogenic. He then describes his own studies on 212 women, most of whom had no complaints and underwent an examination to obtain a health certificate. In determining the incidence of *Trichomonas vaginalis*, he found that of the women examined for the presence of these parasites 41 per cent gave positive results by microscopic test and, in addition to these, 21 per cent gave positive results when cultures were made. The remaining 38 per cent of the women gave negative results. Whereas 526 per cent of the women without vaginal disorder proved to be carriers of *Trichomonas vaginalis*, 29 per cent of the women with vaginal discharge and other disorders were free from *Trichomonas*. After studying the behavior of *Trichomonas vaginalis* as regards acidity, and after determining that the organisms produce no glycogen decomposition and practically no sugar fermentation, the author examined the bacterial flora in cases of infestation with trichomonas. He found the bacterial flora practically the same as in cases without *Trichomonas vaginalis*. He reaches the conclusion that his observations fail to prove the pathogenicity of *Trichomonas vaginalis*.

Newer Aspects of Surgical Collapse Therapy of Pulmonary Tuberculosis H Kunz—p 937

Meincke's Tuberculosis Reaction—Fröhlich reports his experiences with the Meincke reaction in 258 cases. Attention was given to the outcome of the reaction in the various forms of tuberculosis, which Neumann classifies according to their pathogenesis and dissemination into hematogenic, bronchogenic and lymphogenic forms. The author observed no difference in the incidence of the positive reactions whether the mode of dissemination of the cavernous tuberculosis was bronchogenic, hematogenic or lymphogenic. In fibrous tuberculosis and in case of exudates, the reaction was usually negative. Bronchial carcinomas produced only negative results, except when they were complicated by tuberculosis. The author reaches the conclusion that, although the Meincke reaction is of no value for the exact determination of the type of tuberculosis and for the prognosis, it has considerable diagnostic value in the differentiation of pulmonary disorders, as was exemplified by the negative reactions in nine cases of bronchial carcinoma.

Crepitant Sounds in Cases of Pneumothorax—Kirch says that pneumothorax patients often come for consultation before the day that had been appointed for refilling, because they fear that the air has already completely disappeared. They base their fear on the appearance of crepitant sounds on the side of the pneumothorax. The examination of such patients actually reveals the crepitant sounds, so that even the physician suspects that the air has disappeared. Roentgenoscopy, however, discloses that, although the air space has become smaller, the two pleurae do not come in contact at any point. Thus the crepitant sounds cannot be ascribed to pleural friction in the strict meaning of the term. The author suggests that the crepitant sounds originate in the following manner. The patients who make this complaint are usually those who have undergone pneumothorax treatment for long periods. The roentgenoscopy often reveals the visceral pleura as a thick lamella. This condition of the visceral pleura, the changes which develop in the collapsed portions of the lung, the partial atelectasis, lymphatic stasis and so on cause the crepitant sounds in the lung in a certain stage of expansion. The crepitant

sounds are audible, but they cannot be felt with the palpating hand. Crepitation that can be felt with the hand indicates contact between the pleurae.

Clinical Course of Tropical Malaria—According to Tarnogradskiy, involvement of the liver during the very first attacks is much more pronounced in the tropical form than in other forms of malaria. This malarial hepatitis continues to occupy the central position in the pathologic picture of chronic tropical malaria. The hepatic lesion gives rise to jaundice and to the development in many of the chronic cases of a symptomatic hemolytic anemia. It likewise plays an important role in the disturbance of water balance. Manifestations of a toxicosis and the resulting degenerative lesions of the parenchyma of the myocardium, the kidneys and other organs, are likewise the result of profound disturbance of liver function. The hepatitis in the course of time leads to the development of a liver cirrhosis. The liver must therefore be accorded particular consideration in the treatment of patients with tropical malaria. The appearance of manifestations of malarial cachexia in regions in which tropical malaria is endemic calls for renewed treatment with quinine or plasmochin, even in the absence of parasites in the peripheral blood. The frequently accompanying amebiasis and helminthiasis demands thorough treatment. One must exercise great care in prescribing for malarial patients such hepatotropic poisons as arsphenamine, cinchophen or chloroform. The author suggests a predominantly carbohydrate diet accompanied by insulin administration, when necessary, in order not to overload the liver with albuminous foodstuffs.

Treatment of Acute Chorea—Zalkan and Ebich report fifteen cases of acute chorea treated by procaine block of the sympathetic trunk. The treatment was successful in thirteen, the earlier in the course of the disease, the more striking was the result. The effect of the block in the early cases was rapid and in some of the cases abortive. A prompt improvement in the symptoms frequently took place on the day following the injection, all symptoms disappearing in the course of the following four or five days. A decisive improvement was likewise noted in cases of longer duration, but the recovery consumed more time from ten to fifteen days. These patients were given two or three additional injections. The treatment failed in two cases of long duration, one of one year and one of six months, in patients aged 25 and 15 years, respectively. Good results were obtained in recurrences as well as in the recent cases. There were no recurrences in the cured cases. The author did not experience any difficulty in applying the method in children. The method consists of injecting into the region of the renal fossa from 60 to 100 cc of 0.25 per cent solution of procaine hydrochloride on the side of the predominating symptoms. From one to three injections were given.

*Significance of Precordial Leads in Acute Myocarditis V Mortensen—p 617

Precordial Leads in Acute Myocarditis—Mortensen describes two cases of acute myocarditis following undulant fever and influenza respectively. In the first, changes in the precordial leads during the last part of the course were the only certain signs of the heart disorder, the changes continuing for a time after the extremity leads became normal. In the second instance the changes in the precordial leads were an important aid in diagnosis. In both cases the changes in the precordial derivations were considerably more marked than in the extremity derivations and allowed a far more certain judgment as to the course of the disease.

A PLEA FOR A BETTER UNDERSTANDING BETWEEN THE LARYNGOLOGIST AND THE VOCAL TEACHER

CHAIRMAN'S ADDRESS

ROBERT F RIDPATH, M D
PHILADELPHIA

There are a number of facts which, if more generally known, would be of considerable value both to the laryngologist and to the vocal instructor. It is well known that few singers survive the period of vocal instruction. Is this because of inadequate vocal equipment of the pupil or because vocal teachers overlook the importance of certain factors or are we at fault? These are the questions before us.

Have laryngologists ever realized the importance of the part they play in the lives of singers, actors, lecturers and teachers who come for advice when they find themselves in vocal difficulties? It seems to me, after many years of teaching the mechanism of the larynx and voice production, and numerous consultations with vocal teachers and vocalists that we, the laryngologists, and they, the vocal teachers, are both at fault—at fault because of our lack of scientific cooperation. There are few laryngologists who have more than a meager knowledge of the art of vocal training and there are fewer vocal teachers who have any knowledge of the anatomy, physiology or the phenomenon of voice production. It is mainly this unfamiliarity or ignorance of the subject at both sources that is responsible for a great many vocal tragedies. Most of these tragedies could be avoided if the cooperation of which I speak would be employed. Each fault in a voice has its explanation anatomically, physiologically and acoustically and, if the laryngologist and the teacher would cooperate, the proper diagnosis could be more readily arrived at and the proper treatment prescribed, for the fault that the vocal teacher discerns by ear the laryngologist should recognize unmistakably and scientifically by his examination.

When the singer applies to the laryngologist for advice and relief of a throat or voice difficulty, the actual examination of the upper respiratory tract is necessary, but the laryngologist is not doing the patient or himself justice unless a careful history is obtained as to the causative factors in the present trouble. For instance, knowledge must be solicited as to the social life of the patient. Has he been fatigued? Has he any worry or fear or have there been any family difficulties or any sadness in the history of this present illness? All or any of these conditions are of the greatest importance to the vocalist. For instance, the use of the voice

in anger raises the pitch considerably, and fear is often the chief factor of hysterical aphonia or the complete loss of the voice.

From the singer's standpoint, proper breathing and control of the expired air must be evaluated. The speaker may comma or period his sentences as he wishes. He inhales and exhales and makes his pauses where most effective according to his own interpretation of the matter at hand, but the singer must follow the written music, breathing at stipulated intervals, and he is compelled to retain under control sufficient air pressure to vocalize successfully the passage before he may again inhale. We can now visualize the difficulties that might be encountered if free egress or exit of the air flow should be interfered with in any manner.

The correction of the diet is a phase that must be considered. Digestive disturbances can have a decided effect on the mucous membrane and thus change the character of the vocal production. As with an athlete who has overtrained, so there are those who through striving to attain certain ends in a short time overstrain their voices with resultant fatigue of the muscular elements. Rest must be advised for this, or certain forms of humming or exercises must be suggested. I am purposely keeping away from pathologic conditions in this presentation, as I feel that the diagnosis and proper treatment of these would be well and thoroughly taken care of by the laryngologist.

As vocal teachers are dependent on the results they obtain from their students for increased prestige, I feel that, if the physical condition of their prospective pupil were known, they would have a better chance of producing a singer who would be more worthy of their effort.

I have been told on reliable authority that in Italy all vocal aspirants before being enrolled as students in singing schools and conservatories undergo a complete physical examination. As an example, Adelle Borghi, one of the greatest mezzo sopranos Italy ever produced, told one of her American pupils that she, at the tender age of 9, was examined for her physical fitness before her acceptance as a pupil because singing, being an arduous physical exercise, requires a sound physical body, and that was seventy years ago.

The character of the adult voice depends on the size, shape and length of the cords and this again depends on the age of adolescence. Those whose voice assumes the tenor quality, for instance, mature early. The larynx, which up to the beginning of sexual life is infantile in character, grows more rapidly at this time, with resultant diminution in size of the anatomic members and shortness of the cords. This phenomenon also takes place in the female, the earlier her menstrual life begins, the shorter the vocal cords and the higher the vocal pitch. There exist the various characteristics, as the coloratura, the lyrie or the mezzo soprano, according to the age at which sexual life begins. It is thus easily

understood why there are the various ranges of voice, the tenor maturing early and the basso maturing later. Also the tenor is usually of short stature, as is also the soprano, whereas the baritone, the basso and the contralto are of tall and large build. In addition, the tenor is characterized by certain other features, such as a clear and soft skin, a tendency toward a female pelvis and a sparsity of abdominal, chest and other body hair, whereas the basso is tall and thin, with a prominent Adam's apple, and is decidedly masculine in all his bearings. The baritone would naturally come in between these two extremes.

The general characteristics of the body are particularly noticeable in the female. The soprano is decidedly feminine in all her bearings, whereas the contralto has many of the masculine characteristics, such as facial contour and more hair, and even the stride assumes that of the male rather than the short, quick step of the soprano.

It is a fact that most vocal teachers try to make sopranos of all girls and tenors of all men, with resultant failures, whereas if they would consider the individual from the physiologic point of view they would not expect a student who is anatomically unsuited to produce high tonal effects to become a tenor, and vice versa.

Having already mentioned the general health of the student, I feel that each should have a thorough and complete examination made of the heart, lungs, kidneys and intestinal activity by a competent diagnostician, as no one can be expected, when physically unfit, to produce his best vocally. Just so a careful ear examination should be made. An accurate sense of hearing is absolutely necessary for a good voice. If the auditory sense is not normal, how can singers sense whether they are giving forth the proper pitch and tonal effect? The tongue is also an important member of the vocal apparatus and should be freely movable. The palate should be examined as to its height and contour, as it is the sounding board of the voice. Its broad surface collects the sounds and deflects them wholly or partially through the mouth. An examination of the larynx is absolutely essential, as by this means we are not only able to tell whether any pathologic condition is present but also whether the cords approximate correctly and also judge by their length the character of the voice they are fitted to produce normally and anatomically. Many times I have found students striving for higher pitch when their normal range was much lower. The effort of their straining in trying to attain an anatomic impossibility produces vocal nodules, with the ruination of the voice.

As the sinuses and nasal chambers act as resonators, these should be healthy and any disorder or occlusion corrected. No person even with training can produce the tonal quality necessary for perfection unless the proper resonance is present.

After the proper medical examinations have been made and the pupil has been approved for instruction, the laryngologist having also given his opinion as to the vocal sphere in which that particular voice belongs and the teacher having concurred with regard to this category, the real work of training the voice begins.

During cultivation of the voice, many pitfalls are encountered which are not easily discernible by the ear alone. However there are certain definite signs, the beauty of the tone will be lost, a slight tremolo occurs, there may be hoarseness and shrillness, and during scales and runs the voice becomes sluggish not because the pupil is lazy but because the voice refuses to

respond. These are danger signals the neglect of which may lead to real vocal ruin. For this reason it has been said that "voice cultivation is voice deterioration."

This is why I believe the physician is so vitally important in voice cultivation. By periodic examinations the physician can see and sometimes forestall such conditions as inflammation of the cords, vocal nodules, relaxation of the vocal cords and other ills that afflict singers. That the physician is finally called on to treat the pathologic condition is to be deplored because the mischief may be beyond repair, the mechanism being permanently damaged.

Therefore it stands to reason that the art of voice cultivation cannot be left in the hands of the singing teacher alone but is something in which the laryngologist must also participate, and if laryngologists as specialists will give this subject more thought, there may be fewer casualties among singers. It would not then be said that out of a thousand singers only one survives the rigor of vocal training.

This is my plea to the laryngologist to serve the singer in the capacity of scientific adviser and to work along with the teacher during the period of training rather than to be consulted when it is too late and after singers have sung their "swan songs."

FACTORS AND EVENTS ASSOCIATED WITH ONSET OF CORONARY ARTERY THROMBOSIS

A. M. MASTER, MD

SIMON DACK, MD

AND

H. L. JAFFE, MD

NEW YORK

During the past decade, knowledge of the clinical course of coronary artery thrombosis and the pathologic changes associated with it has been increased rapidly. Nevertheless, the actual events which precipitate an attack remain a matter of speculation. Characteristically, an attack of angina pectoris follows physical exertion or emotional stress, and without critical analysis the same factors have been considered responsible for inducing coronary artery thrombosis.

Fitzhugh and Hamilton¹ and others² expressed the belief that coronary thrombosis follows unusual exertion. Riesman and Harris³ and Wolff and White⁴ concurred with them but pointed out that an attack often occurs while the patient is at rest or even in bed. Other authors⁵ found no definite relationship between physical stress and coronary thrombosis.

From the Cardiographic Laboratory and the Medical Services of the Mount Sinai Hospital.

Luten⁶ went so far as to state that the attack invariably occurs in the absence of effort

Similarly, the importance of occupation and social status as factors in coronary thrombosis remains a moot question. Some writers⁷ have agreed with Osler⁸ that the upper classes principally are affected and particularly persons engaged in professional life. However,

TABLE 1—Occupation in 522 Cases of Coronary Artery Thrombosis

Occupation	Number	Incidence
Workers and laborers	196	37.5%
Store workers	26	5.0%
White collar and office workers	52	10.0%
Business men	52	10.0%
Professional people	41	7.8%
Housewives	117	22.4%
None or retired	38	7.3%

a number of writers⁹ have stated that the incidence is practically the same in all walks of life

For some years we have been interested in the factors determining the formation of a coronary artery thrombus.¹⁰ A brief preliminary report has been made, in this paper we will consider a large series in greater detail

MATERIAL AND RESULTS

Eight hundred and seventeen attacks of coronary artery thrombosis occurring in 555 patients were studied. One hundred and eighty-five of the patients were private and 370 ward patients. There were 432 men and 123 women. The ages ranged from 27 to 88 years, the majority of the patients were in the sixth or seventh decade.

Occupations were recorded in 522 cases (table 1). Forty-nine per cent of the men were laborers, skilled or unskilled, and the remaining 51 per cent ran the gamut of the complex social system, including storekeepers, office workers and business and professional men. The women included a few nurses and teachers and some in domestic employment but were in the main housewives. It must be assumed that occupation plays little or no part in the occurrence of coronary thrombosis, since the disease is common in all strata of society.

Similarly, the time of day at which the attacks occurred, as recorded in 371 attacks, was found to exert no influence. None of the four periods—morning, afternoon, evening or night—showed a definite preponderance of attacks, the number in each being 104, 83, 77, 107, respectively. The number of attacks at night, that is, from 7 p. m. to 7 a. m., was approximately the same as during the day, 49.6 and 50.4 per cent, respectively. The exact hour of the onset of the attack was reported in only 183 instances. In this small series 50 per cent of the occlusions began between 10 p. m. and 6 a. m., a period usually devoted to rest and sleep.

We were able to ascertain the circumstances under which the thrombosis occurred in 530 cases (table 2). All the attacks that began while the patient was lying

down or sitting were included under rest. These comprised 21.7 per cent of the attacks. The next largest number (19.6 per cent) occurred during sleep. Before any significance can be attributed to rest or sleep as factors in the onset of an attack, it is important to consider not only the percentage of attacks associated with each but also the fraction of time customarily spent by the patients in resting and sleeping. One third of the twenty-four hours is usually devoted to sleep, and since only 19.6 per cent of the attacks occurred during this period, sleep is probably not a factor. The same is true of rest, for more than one fifth of the day is usually spent lying down or sitting. Therefore, one may conclude that although 41.3 per cent of the attacks began while the patient was asleep or resting, the onset was not contingent on these states.

We designated as mild activity the routine habits of everyday life, at home or in the office or store. The percentage of attacks during mild activity was only 13.6. Under moderate activity (5.3 per cent) were included attacks occurring during actual manual labor as well as while the patient was straining at stool, coughing, running upstairs or shopping. In 18 per cent of the cases the attack began while the patient was walking, in most instances at an ordinary pace but occasionally while he was climbing upstairs or up a hill or walking against the wind. Thus 36.9 per cent

TABLE 2—Attending Events in 530 Attacks

1	Rest (lying down or sitting up)	115 (21.7%)
2	Sleep	104 (19.6%)
3	Walking	95 (18.0%)
	74 in street, 7 up stairs, 5 against cold wind, 2 in snow storm, 2 up hill, 5 after meal	
4	Ordinary mild activity	72 (13.6%)
	21 in home dressing, standing, walking about play ing with children, talking, retiring, etc., 17 in store or office, 8 sitting in car or train, 7 driving car, 8 getting out of bed (usually after previous attack), 4 in doctor's office or clinic, 3 doing housework, 3 taking showers or bath, 3 attending a meeting	
5	Moderate activity (except walking)	23 (4.3%)
	17 working as laborers (painter, engineer, carpenter, baker, tailor, presser, etc.), 5 during bowel movement or straining at stool, 2 coughing, 2 running up stairs, 2 shopping	
6	Unusual or severe exertion	11 (2.1%)
	3 lifting or moving a heavy load, 4 during or immediately after sports or games (football, swimming, dancing, skating), 2 running for train	
7	Trauma	1 (0.2%)
	Fall on chest	
8	During or after meal	28 (5.3%)
	12 light meal (including 2 after cold drink), 16 heavy meal, 5 while walking after meal (under walking), 6 in sleep after heavy meal (under sleep)	
9	Excitement—mental or emotional	27 (5.1%)
	8 playing card or gambling, 6 argument, 3 news of death of relatives, 2 fright (lightning), 2 during basal metabolism and Ruffini test meal, 2 after colitis, 3 miscellaneous	
10	Postoperative	22 (4.1%)
	7 laparotomy, 5 genito-urinary operations, 5 eye, ear, nose and throat operations, 2 leg operations, 1 thoracotomy, 1 tooth extraction, 1 laceration of furuncle, 1 paravertebral block	
11	Infection	10 (1.9%)
	7 infections of upper part of respiratory tract, 2 grip (1 included under meals), 1 bronchopneumonia, 1 erysipelas of face	
12	Gradual onset with increasing angina on exertion	9 (1.7%)
13	No definite onset, no history of pain or other acute symptoms (silent coronaries)	8 (1.5%)

of the attacks occurred during mild and moderate activity and walking. However, since 50 per cent of the day is spent in these activities, more than half of the attacks should take place during work or while the patient is walking if these activities are to be considered factors.

Eleven patients (2.1 per cent) gave a history of an unusual occurrence or severe exertion (table 2) preceding their attacks. Such efforts as lifting a heavy load, running for a train or participating in sports were included. In view of the importance usually attributed

to the rôle of strenuous exertion in the onset of coronary artery thrombosis, the very low incidence of attacks during such activity was surprising and seems to exclude exertion as a factor. Moreover, since this group includes compensation cases, the percentage is probably lower than 21, because patients seeking compensation are apt to emphasize a specific event as the cause of their attacks. It should also be noted that what is strenuous effort for one may be a routine pro-

TABLE 3—Monthly Incidence (1930-1936) of 612 Attacks

Month	Attacks	Incidence
January	75	12.2%
February	43	7.0%
March	48	7.8%
April	48	7.8%
May	56	9.2%
June	44	7.2%
July	54	8.8%
August	50	8.2%
September	46	7.5%
October	46	7.5%
November	39	6.4%
December	63	10.3%
Autumn winter (October-April)	314	51.3%
Spring summer (April-October)	293	48.7%

cedure for another, thus, lifting a 150 pound weight may be no more effort for a stevedore than moving 20 pounds is for the grocer or carpenter. Nor should one expect strenuous effort to be of importance, since quickening of the circulation would not make for thrombosis. If exertion is a factor, the majority of attacks in our series would have occurred during the day, but, as we have shown, the time of day was of no significance and, in the cases in which the exact hour of the onset was obtained, half the attacks began between 10 p. m. and 6 a. m. It is interesting to note that not once did occlusion occur while the patient was playing golf, a sport so often indicted on this score.

There was only one instance of trauma in our series.

Excitement was associated with the onset of the attack in 51 per cent of the cases. Since emotional stress is inevitable in the lives of most people, and because the percentage of attacks following excitement was small, we do not feel that excitement is a factor. It may be noted that only twice did an attack occur during sexual intercourse.

The number of attacks coincident with meals was 53 per cent. The incidence was no greater after a heavy meal than after a light one. In a few instances the attack began after the first mouthful of food or after a cold drink. Walking immediately after a meal was followed by an attack only five times. It thus seems evident that the occurrence of coronary thrombosis after the partaking of food was merely a coincidence, and we therefore cannot agree with the theory¹¹ that a full stomach or one dilated by gas is the usual cause of the disease.

Whether or not operation is a factor in the initiation of coronary artery thrombosis is of considerable practical importance. There are numerous reports¹² of occlusion following all types of operation and anesthesia. The incidence in our series was small, 4.1 per cent, yet it is possible that there is a relation between the two events for the thrombosis usually occurred

within the first three days after operation. Furthermore, cases of thrombosis are extremely rare in the medical services, only four having been recorded in the past seven years.

Campbell¹³ stated that there was a definite association between infection and coronary thrombosis, but Herrick¹⁴ and MacCallum¹⁵ found little evidence of this. Our experience is in accord with the latter view, the incidence of infection in our series being only 1.9 per cent (eleven cases). Nine of these patients had contracted infection of the upper part of the respiratory tract the week before the onset of the coronary artery thrombosis, one had erysipelas and one broncho pneumonia.

It is commonly believed that coronary thrombosis occurs rarely in the presence of heart failure. On the other hand, Luten⁶ expressed the opinion that heart failure is conducive to coronary thrombosis because of the enforced rest and diminished cardiac output. In our series, thrombosis was engrafted on cardiac failure nine times. We believe that this was merely a coincidence, and thus we are unable to confirm either of these views. While nine cases are a considerable number, if heart failure were a factor in coronary thrombosis the latter would be more frequent in our wards, where there are always numerous patients with heart failure who remain in bed for long periods.

Fitzhugh and Hamilton¹ reported that only one attack in 100 cases of coronary thrombosis was induced by the administration of insulin. In our series, twenty patients were receiving insulin regularly, and in only one case were we able to connect the attack with the injection, in this case the administration of insulin had been begun several days prior to the attack. However, we cannot attach too much importance to this circumstance, since the patient also had an eye operation.

TABLE 4—Incidence of Smoking* in 364 Patients

	Males	Females
Nonsmokers	84 (30.8%)	88 (9.5%)
Light smokers	26 (9.6%)	1 (1.3%)
Moderate smokers	57 (21.0%)	3 (3.3%)
Heavy smokers	105 (38.6%)	0
	272	92

* Light 15 cigarettes or 1 cigar or 1 pipeful daily; moderate 61 cigarettes or 2.4 cigars or 2.4 pipefuls daily; heavy 16 or more cigarettes or 5 or more cigars or 5 or more pipefuls daily.

TABLE 5—Incidence of Alcohol Drinking in 379 Patients

	Males	Females
Nondrinkers	145 (61.4%)	90 (9.9%)
Light or occasional	93 (33.0%)	4 (4.1%)
Moderate	33 (11.7%)	0
Heavy	11 (3.9%)	0
	282	97

Further investigation will be necessary to establish a relationship between insulin and coronary thrombosis, as has already been noted regarding insulin and angina pectoris.

Several authors¹⁶ have found the incidence of coronary artery thrombosis greatest in cold weather.

Wood and Hadley¹⁶ reported ninety-five cases during the autumn and winter and only fourteen in the spring and summer. Of 612 attacks in our series (table 3), however, 51.3 per cent occurred between October and April and 48.7 per cent in the spring and summer. The element of cold, therefore, seems to have no role in the formation of a coronary thrombus.

Recently, much has been written concerning the important effect of the use of tobacco on cardiovascular disease, including thrombosis. We therefore investigated this point. Table 4 shows that one third of the men and practically all the women were nonsmokers. Furthermore, the proportion of heavy and moderate smokers did not differ from that of society in general. Therefore, we believe that tobacco has no influence on the occurrence of coronary thrombosis. White and Sharber¹⁷ came to a similar conclusion concerning coronary sclerosis.

A glance at table 5 makes it obvious that alcohol also has no role in coronary thrombosis, since more than half the patients did not drink at all. In fact, it may protect, since only 4 per cent of our patients were heavy drinkers. It is noteworthy that in only one case did occlusion follow a drinking bout.

COMMENT

From the foregoing report it would seem that the onset of coronary artery thrombosis during the various states considered was merely a temporal coincidence and that no specific factor precipitates an attack. This contrasts with the situation in angina pectoris, which is often confused with coronary thrombosis. While both conditions are probably manifestations of a metabolic disturbance, as Libman¹⁸ stated, and while the local pathologic process is sclerosis of the coronary artery, yet the two conditions differ widely. Angina pectoris is a functional syndrome. It appears when there is temporary insufficiency of coronary blood flow as a result of exertion or reflex spasm. The nervous element is paramount. Although some attacks of angina pectoris occur without discernible cause, the majority are definitely related to specific acts, such as playing golf, walking against the wind, eating a meal or excitement. The attack is relieved by glyceryl trinitrate. Coronary thrombosis, on the contrary, occurs irrespective of rest, activity, excitement or emotion and season or temperature and is not helped by glyceryl trinitrate. It is not our intention to minimize the value of physical and mental rest in the treatment of chronic disease of the coronary artery, but thus far medicine has been unable to prevent the formation of a thrombus.

SUMMARY

A statistical study of over 800 attacks of coronary thrombosis was made to determine what factors may have initiated the thrombosis.

Coronary thrombosis occurred in all walks of life and in all types of occupations.

Although 40 per cent of the attacks occurred during rest or sleep, this was probably a coincidence, since half the day is ordinarily spent in these states.

Exertion, even severe, was of little or no significance in the precipitation of an attack. This held good for walking, straining at stool, coitus and playing golf.

Excitement, ingestion of food, infection, tobacco, alcohol, heart failure, time of day and season of year were found to have no significance.

¹⁸ Libman Emanuel. Symposium Angina Pectoris with Special Reference to Coronary Artery Disease. *Bull. New York Acad Med* 11:427 (July) 1935.

The effect of operation and of insulin require further study.

Although both angina pectoris and coronary artery thrombosis have the same underlying pathologic condition, namely, coronary sclerosis, they differ entirely in respect to the exciting cause of the attack.

anesthesia³ and in orthostatic hypotension,⁴ and for the relief of spasm affecting the gastro-intestinal tract⁵. The stimulating effect on the central nervous system has led to observations on the effect of benzedrine in many psychiatric and neurologic conditions, including narcolepsy,⁶ disorders of mood and affect (chiefly depression⁷), postencephalitic parkinsonism,⁸ psychoneurosis,⁹ and to observations on its effect on normal persons and on those¹⁰ suffering from states of exhaustion¹¹.

The method by which benzedrine produces a stimulating action on the central nervous system and the part of the brain which it stimulates is unknown. Marked stimulation of the nervous system is the most striking effect of the drug. The long duration of this effect is noteworthy. From the evidence which has so far accumulated, benzedrine does not appear to be toxic in usual doses nor does it seem to be habit forming.

This report, which supplements a previous one,¹² is concerned with the effects of administration of the drug to 100 patients during a short time and to forty-four patients during periods varying from two weeks to eight months. All of these patients were carefully examined and had no detectable evidence of organic disease. The drug was administered orally in the form of the sulfate, in doses of from 2.5 to 20 mg before breakfast and frequently the dose was repeated at noon. In all our work the sulfate was used. A placebo tablet identical in appearance with that which contained benzedrine, was administered on occasions and failed regularly to cause any change of symptoms.

We have divided the 100 cases, according to the symptoms, in three groups under the headings (1)

chronic exhaustion, (2) psychoneurosis and (3) depression. To distinguish clearly between a state of chronic exhaustion and a psychoneurosis often is difficult if not impossible. For the purposes of this presentation, states of chronic exhaustion may be considered to be characterized by persistent sensations of fatigue, lack of energy and lassitude, for which no organic cause can be determined. These sensations may be part of a syndrome of biologic inferiority or may result from environmental difficulties, overwork or infections. A description of many of the features of this syndrome, and justification for the diagnosis, have been given previously by Macy and Allen.¹³ The term "psychoneurosis" is used in this presentation to designate the condition of a group of patients whose chief symptoms were nervousness, anxiety, restlessness, irritability, inability to relax and who had numerous somatic symptoms. In this group of cases fatigue ordinarily was not a prominent symptom. It is frequently difficult to evaluate the results of any form of treatment if patients are subject to nervous and mental disorders and fatigue states, because of the marked variability in the course of these conditions. We cannot say definitely that the use of benzedrine was responsible for all the beneficial effects noted in our study, for reassurance of the absence of organic disease, correction of environmental difficulties and rearrangement of methods of living, as well as other factors, may have contributed significantly to improvement.

CHRONIC EXHAUSTION

Immediate Effects—The effects of one or two doses of benzedrine on thirty-two patients who had chronic exhaustion are noted in table 1. The condition of twenty-five, or 78 per cent, of the patients was improved following the use of benzedrine. In some instances the results were spectacular, leading to complete disappearance of exhaustion, marked exhilaration and increased capacity for physical and mental work. Along with this there were, in some cases extra version of thought and activity, speeding of mental processes, cheerfulness, elation and loquaciousness. Vague neuromuscular aches and pains and consciousness of abdominal discomfort frequently were greatly benefited or entirely relieved. When symptoms such as nervousness, anxiety, restlessness and irritability were present, they were frequently uninfluenced or even accentuated. Many of these patients stated that they felt "jittery" or stimulated and that they noted dryness of the mouth, palpitation, tremor and excessive sweating. Some of these unpleasant symptoms which frequently followed the use of the drug and outweighed its beneficial effects may have been the result of the administration of the rather large amounts of the drug that were required to relieve fatigue.

Effects of Prolonged Administration—The effects of benzedrine administered daily for from two weeks to eight months, in doses of from 2.5 to 20 mg once or twice daily, were studied in twenty-three cases of chronic exhaustion in which the immediate effects of the drug were beneficial. The results are indicated in table 2. Improvement of the condition of seven patients (30 per cent) continued for from three weeks to four months while they used the drug but they discontinued the use of it after variable periods because improvement was only slight because of the subsequent development of undesirable effects or because the

effect of the drug eventually wore off entirely. As often expressed by the patient, "the effect wore off" or "I seemed to get used to it." Five patients (22 per cent) felt improved during use of benzedrine over periods of from one week to one month but discontinued the use of it because unpleasant effects noted previously continued and offset the beneficial effects. Eleven patients (48 per cent) are continuing to use benzedrine after periods of from one to eight months and feel that the favorable effects have persisted.

TABLE 1—Immediate Effects of Administration of Benzedrine

Diagnosis	Number of Patients			Total	Percentage of Patients Improved
	Worse	No Change	Improved		
Psychoneurosis	12	7	16	35	45.7
Depression	5	4	21	30	70.0
Exhaustion	3	4	25	32	78.1
Total	20	15	62	97*	63.9

* Three patients not included in the table had depression associated with chronic alcoholism.

A review of the records of the patients whose condition was improved and of those for whom improvement was only temporary or was associated with unpleasant symptoms failed to reveal any distinguishing features that could be used to explain the divergent results. The following report of a case illustrates the gradual loss of effect that may occur even though the immediate result was remarkable.

CASE 1—A man aged 27, came to the clinic complaining of headaches, constipation and marked fatigue of three years' duration. He was so fatigued that he had been unable to complete his studies as a law student. Extensive clinical, roentgenologic and laboratory examinations failed to reveal evidence of organic disease, and a diagnosis of chronic exhaustion was made. The patient was given 20 mg of benzedrine before breakfast and 20 mg before lunch, following which he stated that he noticed very marked relief of fatigue and a markedly increased desire and capacity for physical and mental effort. He felt that "a cloud had been lifted from his brain"; he regained his former confidence and "felt normal for the first time in three years." During the day he played twenty-seven holes of golf without particular fatigue whereas previously nine holes had been thoroughly sufficient to exhaust him. Previously noted muscular aches and vague abdominal discomfort disappeared. The patient was advised to take benzedrine in amounts of 20 mg before breakfast and 10 mg before lunch for a trial period. One month later he reported that his condition was so much improved that he seriously contemplated returning to law school. Five months after his examination at the clinic, his condition was still much improved. He had returned to law school and was working continuously with reasonably good success. However, he was taking benzedrine in a dose of 10 mg every three days because otherwise it lost its effect. Seven months after his first visit to the clinic he reported complete exhaustion at the end of the day and inability to concentrate, which were symptoms of which he originally complained. Benzedrine not only was no longer useful in overcoming these symptoms but it made him "terribly irritable."

The following case is illustrative of persistent improvement following administration of benzedrine for eight months.

CASE 2—A woman, aged 28, came to the clinic complaining of exhaustion of three years' duration. The feeling of tiredness had begun while she was teaching and had progressed to such an extent that she had been obliged to give up her work. She rapidly lost interest in all activities and for one year she had required from twelve to thirteen hours of sleep daily. Despite the fact that her appetite was large she felt that she did not get "any energy out of her food." Extensive examination failed to reveal evidence of organic disease and a diagnosis of chronic

exhaustion was made. The patient was given 20 mg of benzedrine before breakfast and 10 mg before lunch following which she stated that she obtained marked relief from fatigue and that she felt better than she had felt for four years. The improvement was so marked that she did many things, such as cleaning her room, which she had not done for a long time. The patient was advised to take benzedrine in amounts of 20 mg before breakfast and 10 mg before lunch for a trial period. At the end of eight months during which the daily dose of benzedrine had been continued, the patient reported that she still experienced very marked increase of energy, increase of desire and capacity for physical and mental effort, as well as a marked feeling of well being and exhilaration. There had been no change in blood pressure which had been normal when she was originally examined at the clinic. Her appetite had been persistently lessened since taking benzedrine and it had been a little more difficult for her to sleep than it was previous to her taking the drug. However, the patient wrote that she felt "like living."

PSYCHONEUROSIS

Immediate Effects—The immediate effects of benzedrine on a group of thirty-five patients on whom a diagnosis of psychoneurosis was made are presented in table 1. The dominant symptoms noted were nervousness, anxiety, inability to relax, and lack of energy. If exhaustion was present, frequently it was improved but the dominant symptoms were frequently exaggerated. In many instances it was possible to predict beforehand the results to be obtained with benzedrine in this group of cases. It will be noted that the percentage of psychoneurotic patients who obtained immediate good results was not as large as was the corresponding percentage of patients who had chronic exhaustion and we have noted, in addition, that the degree of improvement of patients with psychoneurosis was less striking. Many of them noted that unpleasant symptoms were accentuated by administration of the drug. Because of the foregoing observations, the effect of prolonged administration of benzedrine on patients with psychoneurosis has not been studied.

DEPRESSION

Immediate Effects—Of a group of thirty patients who were suffering from depression the immediate effects of benzedrine were striking on twenty-one, or

TABLE 2—Effects of Continued Administration of Benzedrine in Cases of Chronic Exhaustion*

Result	Cases		Duration of Treatment Weeks
	Number	Per Cent	
Continued improvement	11	47.8	1.32

Total	23	100.0	

* The immediate effect of the drug was beneficial in all cases.
† After variable periods because (a) improvement was slight (b) effect wore off (c) undesirable effects developed.
‡ Because a isolated unpleasant symptoms persisted.

70 per cent (table 1). These patients were carefully selected, depression, with mental and physical slowing was the predominant feature of the clinical picture. Patients who had marked anxiety and physical and mental hyperactivity associated with depression were not ordinarily benefited by benzedrine, for the symptoms mentioned were accentuated. Of twenty patients who had simple or reactive depression, fourteen experienced marked relief, four noted no change and the condition of two became worse. Of ten patients who were in the depressed phase of manic depressive psychosis, seven experienced marked relief and three

noted exacerbation of symptoms. The patients who experienced relief were not severely depressed.

Three patients not included in table 1 who had depression associated with chronic alcoholism were greatly benefited by benzedrine, which appeared to act as a supplementary stimulant.

Effects of Continued Administration—Although the immediate results of administration of benzedrine to depressed individuals were excellent, our experience with its continued use in this group has been disappointing, as shown in the chart. Twenty-one patients whose initial response to benzedrine was excellent continued to take the drug for variable periods. Thirteen had simple depression and eight had the depression of a manic-depressive psychosis. Of these twenty-one depressed individuals, six reported that in spite of continued medication the initial favorable results were not repeated after the first week. Because benzedrine failed to relieve their condition, an additional six

Decreasing effect of continued administration of benzedrine to patients who are in states of depression

patients discontinued its use in one month and three more patients discontinued its use at the end of three months. Six remain to be accounted for. Of these, one discontinued use of the drug before six months had elapsed and five reported after six months that they continued to obtain relief from the medicine. It is obvious that relief of depression as a result of administration of benzedrine is temporary in many instances.

The following report of a case is illustrative of the persistent improvement following continued administration of benzedrine.

CASE 3—A man, aged 45, was seen at the clinic in August 1936. Since 1918 he had suffered from repeated episodes of depression, which had alternated with periods of mild exaltation. When examined at the clinic he had been depressed for a year and was unable to work. Examination of the patient did not reveal significant abnormalities. Twenty milligrams of benzedrine given by mouth resulted in marked relief and the patient was dismissed with instructions to take 10 mg of benzedrine in the morning and again at noon. Three months later he wrote the following letter:

"As soon as I started taking the benzedrine the depression and feeling of fear left me at once. It felt like the 'do or die' emotion had come to life again and had driven the fear feeling

out of my mind, or in other words it made me feel like I felt before under normal conditions when I have been at the best of vigour. Due to luck I was able to obtain work. I was able to put it over the first week and the firm was satisfied, and as time has gone on I have gathered more confidence in myself. I now sleep well without the use of sleep tablets, and I do not have those terrible regrets in the morning but I still have a strong tendency to day dream and am a bit weak yet to withstand any real disappointment."

The following report of a case illustrates gradual loss of effect from continued use of benzedrine, even when effects of the initial administration were excellent.

CASE 4—A man, aged 52, was examined at the clinic in July 1936 because of mental depression. In 1925 he had suffered from depression for six months following financial reverse. He had recovered completely from this episode but there had been a recurrence in 1927 which had lasted one year. In 1930 he had become depressed again, this state had lasted for two years but he again had recovered completely. The episode of depression at the time of examination had begun in 1935 and had continued with no remission. During the states of depression the man was obsessed with suicidal thoughts and it was only with the greatest difficulty that he could tend to his personal needs. He was unable to work. Following administration of 20 mg of benzedrine there was a marked change in mood. The patient became happy and confident and there was marked increase in psychic and motor activity. He went to two motion picture shows on the day he took the benzedrine, he said that he was able to follow the action closely and that he had enjoyed himself for the first time in a year. He was dismissed with instructions to take 10 mg of benzedrine in the morning and again at noon. Two months later he was again examined at the clinic. He complained that although he had continued the daily use of benzedrine, and had been greatly relieved for a month, the drug was failing in its effect. His depression had returned and it was impossible for him to work. The dosage of benzedrine was increased to 30 mg a day but no benefit resulted. Medication has been continued for six months but the patient never again has experienced the marked relief that was so evident during the first few weeks of administration of benzedrine.

UNFAVORABLE EFFECTS

The unfavorable effects of one or two doses of benzedrine have been noted previously and include exaggeration of nervousness, apprehension and anxiety, a feeling of being "fidgety" or "jittery" and insomnia, excessive sweating, dryness of the mouth, light headedness, irritability and melancholia. Some patients who have continued to take benzedrine for periods of weeks or months occasionally have noted persistence of the symptoms or development of them. We have not noted unfavorable gastro-intestinal symptoms, such as abdominal cramps and an increased desire to go to stool, which other observers¹⁴ have reported.

Loss of weight, apparently resulting from reduced appetite and increased activity, have been noted by some observers¹⁵ as an unfavorable effect of the drug. It has been suggested that the relative anorexia result from diminished tonus of the gastro-intestinal tract. Of the twenty-three patients with chronic exhaustion who took benzedrine from two weeks to eight months, two reported loss of 20 pounds (9 Kg) after using benzedrine for two and four months respectively. Two patients, however, reported a gain of 5 and 6 pounds (2.3 and 2.7 Kg) respectively and the weight of the remainder did not change significantly. One possible harmful effect of prolonged administration of benzedrine may be encountered if the drug is given to patients whose exhaustion or fatigue is a protective

¹⁴ Davidoff, Eugene and Reifstein, E. C. The Stimulating Action of Benzedrine Sulfate. A Comparative Study of the Response of Normal Persons and of Depressed Patients. *J. A. M. A.* 105: 1, 1937 (May 22).

¹⁵ Nathanson, Davidoff and Reifstein.

symptom, abolishment of the exhaustion or fatigue may result in expenditure of energy beyond the capacity of the individual

There are no reports in the literature to suggest that use of benzedrine leads to formation of a habit, and because of its chemical structure one would not anticipate such an effect. The possibility of formation of a habit is not excluded, however. The first patient with narcolepsy to whom Prinzmetal and Bloomberg⁶ reported giving the drug is still taking the same dose after three years.

That benzedrine may cause elevation of the blood pressure for periods varying from five to seven hours has been noted by several observers.¹⁶ In at least one case (case 5) when benzedrine was given in relatively small doses to an elderly patient who had hypertension, undesirable increases in blood pressure and cardiac symptoms were produced.

In the following two cases, alarming symptoms referable to the heart arose in the course of treatment with benzedrine.

CASE 5—A woman, aged 72, who had received treatment for carcinoma of the breast and who had essential hypertension came to the clinic because of a feeling of depression of several months' duration. She stated that in the morning she frequently felt "blue" "that life was hardly worth living" and that she seemed to be exhausted. There were no significant cardiac symptoms and examination of the heart gave objectively negative results. The systolic blood pressure in millimeters of mercury was 140 and the diastolic blood pressure was 80. A diagnosis of depression was made. Following administration of 20 mg of benzedrine before breakfast the patient's condition was remarkably improved. Exhaustion disappeared completely and she felt that the day was not long enough for doing the things she wanted to accomplish. The patient was advised to continue to take benzedrine in amounts of 20 mg before breakfast, under the care of her physician. The dose was subsequently reduced to 10 mg. The improvement originally noted continued, but about two months after the patient had begun to use the drug retrosternal discomfort and dyspnea developed, symptoms interpreted by her physician as being due to coronary sclerosis. The blood pressure was 180 systolic, the diastolic pressure was not recorded. Benzedrine was discontinued.

CASE 6—A man, aged 46, came to the clinic because of marked fatigue, abdominal discomfort and mushy stools. He was so exhausted that it was difficult for him to force himself to work for several hours and many simple routine duties required great effort on his part. Physical examination gave essentially negative results and extensive roentgenologic and laboratory examinations did not reveal any abnormalities. A diagnosis of chronic exhaustion and irritable gastro-intestinal tract was made. All symptoms were relieved following administration of benzedrine. By using 10 mg before breakfast for four months, the patient continued to note the remarkable improvement that he had experienced originally. At the end of this period of four months he had several attacks of severe pain in the chest, which he related to his heart. Although objective examination of the heart by a competent cardiologist gave negative results, it was felt advisable to discontinue the use of benzedrine.

DOSAGE

Benzedrine was administered orally to our patients in doses of from 10 to 20 mg before breakfast and frequently the amount was given again at noon. When the drug is taken after noon, insomnia usually results.

It has been our experience that, if the condition of a patient fails to improve with one of the doses noted, he will not be benefited ordinarily by larger amounts of benzedrine. Many of the patients with exhaustion and depression whom we have observed, and who have taken benzedrine over a period of weeks or months, have found that they were able to reduce the dose to as little as from 2.5 to 5 mg before breakfast, with continuation of good results. In other cases 10 mg in the morning and from 2.5 to 5 mg at noon will maintain a favorable effect. Occasionally patients find that intermittent use of the drug proves more satisfactory than continuous administration. One fortunate quality of benzedrine is that the effects of its administration almost always can be determined in one day. If there is no beneficial effect from its administration before breakfast and lunch on one day, it appears useless to administer it over longer periods.

Benzedrine does not appear to be toxic in the doses that should be utilized clinically. Hartung and Munch¹ found the minimal lethal dose of the hydrochloride of benzedrine to be 25 mg for each kilogram of body weight of rats and rabbits.¹⁷ Solomon and his associates¹⁸ have given as much as 160 mg a day for three weeks to a man without apparent harmful effect, and Davidoff and Reifenstein¹⁴ have administered 200 mg in one day to a patient without severe reaction.

COMMENT

Although the initial results that follow the administration of benzedrine to patients who are in states of chronic exhaustion and depression are favorable in a high percentage of instances, it is obvious that continued use of the drug lessens its effectiveness. Thus, our studies show that although the initial effects of the administration of benzedrine are favorable to about 70 to 80 per cent of patients who are in states of exhaustion that are not due to organic disease, and to about the same percentage of patients who are in states of depression, the percentage of favorable effects decreases significantly if administration of the drug is continued for weeks or months. This is in sharp contrast to the results of the treatment of narcolepsy, reports of which indicate that it continues to respond uniformly and favorably to administration of benzedrine for as long as three years. If the results of our studies of the continued administration of benzedrine to patients who are in states of chronic exhaustion or depression are confirmed, it will become apparent that the usefulness of the drug in treatment of these conditions is substantially limited. Observations over longer periods of time than those which we are reporting may show still further limitation of the use of benzedrine.

It is probable that eventually benzedrine will be found to have its greatest value in the treatment of chronic exhaustion or depression when it is used temporarily or perhaps intermittently. While it appears to us that in states of exhaustion benzedrine may simply decrease awareness of fatigue, we are uncertain whether this is the result of stimulation of the central nervous system or of sympathomimetic activity. From our experience it appears that the field of usefulness

17 Since this paper was presented W E Ehrlich and F B Krumbhaar (The Effects of Large Doses of Benzedrine Sulfate on the Albino Rat. Functional and Tissue Changes. *Ann Int Med* 10: 1874-1888 [June] 1937) have reported studies on the effects of benzedrine sulfate on the albino rat. They reached the conclusion that the minimum lethal dose of benzedrine sulfate given subcutaneously to rats is from a hundred to a thousand times per kilo the usual therapeutic dose given man orally. The greatest nontoxic dose is that which fails to produce transient variations appears to be from 2 to 5 mg per kilo in other words about 10 to 50 times per kilo the usual human therapeutic dose.

of the drug in the conditions just named has been gradually narrowed. It is of interest to note that the effects of administration of benzedrine vary widely when it is used in treatment of apparently similar clinical conditions. It seems impossible, therefore, to predict results in any specific instance, only by actual trial can one determine effects.

While the usual initial dose of benzedrine given our patients was from 10 to 20 mg twice daily, many of them noted that as little as from 2.5 to 5 mg, taken once or twice daily, was adequate. Such relatively small amounts may eliminate or reduce unpleasant effects. Inexplicably, two of our patients, one of whom had chronic exhaustion and the other depression, have continued to feel well for several months after discontinuing the use of benzedrine. This suggests that improvement following use of the drug may not be the effect of benzedrine entirely.

Because some of the startling results which follow administration of benzedrine have been widely commented on in the medical and lay press,¹⁸ the drug has rapidly acquired a vogue for all sorts of conditions. People have kept themselves awake and alert for unreasonably long automobile drives and students have utilized the drug, in many instances unwisely, for stimulation and acceleration of mental processes during examinations. In such instances more common sense and less benzedrine are ordinarily advisable. It is worthy of note that Blackburn,¹⁹ in a study of forty-eight persons, many of whom had disturbances of emotion and mood, reported that these persons, following administration of small doses of benzedrine, increased the score obtained in an intelligence test by an average of 8 per cent. It is also of interest to note that some persons who have indulged in too large quantities of alcohol may find that the characteristic morning "hang over" is greatly benefited by benzedrine.

The indiscriminate use of benzedrine cannot be too severely criticized. It is never advisable, in states of exhaustion, to substitute its use for careful search for the causes of the exhaustion and the correction of them if this is possible. While, as far as we know, toxic effects from administration of benzedrine have not been noted, the possibility that they may occur must be considered. It should be particularly emphasized that benzedrine is a stimulant and therefore that it probably does not fundamentally and permanently alter a psychotic disorder or a state of chronic exhaustion or neurosis. Whether it is logical and safe continuously to stimulate an individual who presents such a disturbance is a question which cannot be answered at present. We feel that until further observation is made it probably will be unwise to recommend the continuous use of benzedrine except to patients who are less than 60 years of age, who present no evidence of hypertension or cardiac disease and who can be closely observed by a physician.

SUMMARY

The immediate effects of oral administration of benzedrine to a group of 100 patients in which after careful examination, diagnoses were made of chronic exhaustion, depression and psychoneurosis, were beneficial to approximately 80, 70 and 46 per cent respectively. In some instances the results were spectacular.

The effects of the continued administration of the drug were less favorable. Of the patients initially benefited, about 50 per cent who had chronic exhaustion and 25 per cent who had depression continued to receive benefit for periods of from one to eight months.

Benzedrine is a stimulant and therefore apparently does not fundamentally and permanently alter a psychotic disorder or a state of chronic exhaustion. Whether it is logical and safe continuously to stimulate individuals who present such disturbances is a question that cannot be answered at present.

RELATION OF THE FASCIA LATA TO CONDITIONS IN THE LOWER PART OF THE BACK

FRANK R. OBER, M.D.

BOSTON

The object of this paper is to show what has been learned to date from the results of fasciotomy on patients with lame back and sciatic pain. Early in the winter a general questionnaire was sent out to the members of the American Academy of Orthopedic Surgeons and others asking them to send in the number of patients operated on by them and the results obtained and to make any comments on their observations. Forty-one reports were received, giving data on 340 cases. To these are added seventy-five reports from the clinic with which I am associated, making a total of 415 cases from which to draw conclusions. Of the 415 patients, eighty-four (21 per cent) obtained no relief, seventeen (4 per cent) showed only partial relief and 314 (75 per cent) had complete relief. The symptoms were relieved immediately or after intervals up to one year. The average time before relief took place was about three months.

It is hoped that what has been learned from analysis of the questionnaires will bring out some points which are necessary for arriving at a proper diagnosis and which will make the indications for the operation more specific, although it will probably be some time before more definite rules of procedure can be laid down.

HISTORY

Several important factors are to be considered in arriving at a diagnosis if one recognizes that fascial pull in the lower extremity has any relation to conditions low in the back. First there is the history of the condition as related to body mechanics before any story of lame back enters the picture. Have there been any postural disturbances? What is the favorite position in bed? Is the patient able to bend over and touch the floor with his hands when his knees are held straight? What positions induce or aggravate the pain low in the back and the sciatica? How are these conditions affected by sitting, standing, stooping, twisting and walking? Most persons who have difficulties in the lower part of the back associated with contracted fasciae latae lie on their sides with the knee or knee-flexed. Lying on the back or the abdomen usually makes them more uncomfortable.

The history, of course, should be as complete as possible regarding the many other factors which are

known to cause lame back. These factors are sufficiently well known so that it is unnecessary to discuss them in detail.

PHYSICAL EXAMINATION

Any patient who complains of lame back should have a thorough general examination, including neurologic tests and adequate roentgenograms of the back. This means anteroposterior, stereo, lateral and oblique views of the affected regions.

In cases of bilateral sciatic pain and in cases of diminished or increased reflexes, a lumbar puncture should be considered to rule out intraspinal lesions. If the fluid shows increased protein a test with iodized oil may be necessary. Examination of the rectum should not be overlooked. The local examination should be made with the patient standing, if he can stand, and with his back to a good light. His standing position should be noted from his head to his feet, from the front, side and back. One must pay attention to any increase or decrease in the normal physiologic curves and observe whether there is structural or functional curvature of the spine and whether it is to the left or to the right. There may be limitation of forward bending either by irritation of the spine itself or by shortening of the posterior muscles of the legs. Does the patient stand with a list to the side, and is it on the sciatic side or the opposite one? Is the list increased on forward bending? Is there restriction of lateral or backward bending and rotation? Is the patient able to reverse his lumbar curve in forward bending? Are the spinal muscles in spasm?

The patient should have the same tests while sitting with the knees flexed, and restriction of forward bending should be noted when he is in the sitting position with the knees held extended. Areas of tenderness along the spine and about the ilio-lumbar angle and the sacro-iliac joints should be noted. Tenderness and muscle spasm along the superior part of the gluteus maximus muscle is constant with pain low in the back. Tenderness about the posterior aspect of the greater trochanter is common with fascial contracture. In cases of sciatica moderate pressure along the posterior edge of the iliotibial band just above the trochanter, will often increase the pain along the sciatic nerve.

The patient should be tested for limitation of straight leg raising. This is usually pronounced when sciatica is present and causes a good deal of pain. It may be due, as many have stated, to short hamstrings. It may be due also to contracture of the gluteal fascia or to spasm of the gluteal muscles. It was surprising to note in the answers to the questionnaire how few writers recorded whether or not there were curves in the spine, and only a very few recorded Ely's test, which has been described elsewhere.¹ I believe that a positive result in Ely's test means only contracture of the anterior structures of the thigh. The reaction is usually negative after a thorough fascial section.

The abduction test has been added to these tests, since it has been observed for many years that in cases of infantile paralysis contracture of the iliotibial bands keeps the spine in lordosis when the legs are extended. It is well known that a lordotic spine may be a painful spine but this of course is not true in every case. The drag of a low prominent abdomen often produces lordosis which may or may not be accompanied by pain. If this is so, then other conditions producing lordosis should show symptoms although they may not appear until after trauma, often

very slight, precipitates the trouble. In previous articles² it was stated that when the maximum amount of fascial contracture is on the side and in front of the femur, the spine is held in lordosis, and that if the contracture is posterolateral the lumbar curve is flattened. The former condition is common, the latter is rare. Either condition may be associated with pain low in the back and sciatica. Unilateral contracture may produce lateral curvature of the spine.

THE ABDUCTION TEST

Since so many persons do not clearly understand the making of the abduction test, it would appear that the explanation and photographs which appeared in the first publication¹ on the subject were not sufficient. Therefore, I will try to describe the test more specifically, as follows:

1 The patient lies on his side on a table, the shoulders and pelvis being perpendicular to the table.

2 The leg on which he is lying is flexed at the knee, and the hip is flexed and kept flexed to flatten the lumbar curve.

3 If the patient is on his left side the examiner places his left hand over the patient's hip in the region of the trochanter to steady him.

4 The right leg is flexed to a right angle at the knee and is grasped just below the knee with the examiner's right hand, the leg and ankle being allowed to extend backward under his forearm and elbow.

5 The right thigh is abducted widely and then hyperextended in the abducted position the lower part of the leg being kept level and care being taken to keep the hip joint in a neutral position as far as rotation is concerned.

6 The examiner slides his right hand backward along the leg until it grasps the ankle lightly but with enough tension to keep the hip from flexing.

7 The thigh is allowed to drop toward the table in this plane. (Caution: Do not bear down on the leg.) If the fascia lata and the iliotibial band are tight the leg will remain more or less permanently abducted. If the hip is allowed to flex or internally rotate, the iliotibial band becomes relaxed and the leg falls from its own weight.

8 The same procedure for the opposite side is followed in every case.

In some cases the pain on one side can be increased by doing the abduction test on the opposite side. The pain will be increased in these cases also if the patient is asked to stretch his tight iliotibial band on the affected side while standing and leaning the hip toward a table, keeping his body upright.

It is not the intent of this paper to treat lame back and sciatic pain as if all the ills in the lower part of the back were due to disturbances of the fascia lata. In many instances the contracted fascia lata has nothing at all to do with the underlying condition, for example in cases of malignant growth, spinal tumor, arthritis, bad posture or numerous other conditions that are often at the bottom of the patient's troubles with his back.

One writer stated that he believed all thighs remain in abduction when the abduction test is done. Several said that they had never seen positive results in the abduction test in any case of lame back or sciatic pain. According to my experience, the abduction test is not always positive. Many persons who have no symptoms

referred to their backs exhibit an abduction sign and Ely's sign and limitation of straight leg raising. They do, however, have the mechanical set-up for the production of such symptoms if there is an exciting cause.

There are two analogies. First, many patients have astigmatism but do not have headaches. Second, a great many people have highly arched feet without the symptoms of foot strain, and by the same token many patients have severe symptoms of strain in such feet. If these two analogies can be adequately explained, then numberless other conditions can be clarified. It is also true that many persons have lame back who do not have fascial contracture.

The point is that in cases of backache in which the x-ray examination reveals nothing significant and there is abduction contracture, usually associated with Ely's sign, and limitation of straight leg raising, some method of therapy should be instituted to overcome this condition.

ETIOLOGY

Normal persons who lie in bed for a long time during a severe illness can and do acquire contracture. It is possible that the pernicious habit of keeping an infant's legs abducted and externally rotated by the wedging effect of voluminous diapers over a long period may cause mild abduction contracture. Certainly the position is favorable for such a condition to occur. Green, in his studies of children during the first six years of life, noticed that when a child first attempts the erect position he stands with knees and hips flexed. It may be that children who learn to stand late in infancy are longer in overcoming this position and that contracture thus develops as a result of delay in standing and walking.

Perhaps if it were known why some people have highly arched feet or certain facial characteristics it would be possible to answer the question about short posterior muscles of the legs and fascial contracture. All physicians who treat poliomyelitis know that contracture will develop if the patient is allowed to assume bad positions. This is especially true with relation to the hips. If the child lies with his hips flexed, hip flexion may result. If he lies on his back with his legs in the frog position, he gets abduction contracture and often flexion contracture. Limitation of straight leg raising and shortening of the posterior leg muscles are common complications of poliomyelitis. Some of the persons who answered the questionnaire stated they had never seen lame back follow these contractures in cases of poliomyelitis. However, lame back does occur in such cases. One reason it is not common is probably that the legs are so weakened by paralysis that the patient does not do things which hurt his back.

POSTOPERATIVE RESULTS

In eighty-four cases there was no relief or the symptoms recurred. In a few cases the symptoms of lame back were increased.

In most of the cases in which there was no relief there was either a new growth bad arthritis or an anomaly of the spine. In cases in which there was a recurrence, the tight fascia on the opposite side was at fault or else an incomplete operation had been done, i. e., the intermuscular septums were not divided or the anterior portion of the fasciae was not, especially that around the tensor fasciae latae and the sartorius. In one of my cases it was necessary to go down to the rectus femoris before the fascia was freed.

The reason for an increase after fasciotomy in the symptoms referred to the back may be explained. It

does not matter much how a back is strained, the symptoms of strain are about the same, i. e., pain, muscle spasm and limitation of motion. When fascial structures which have been contracted for years exert pull on a spine that holds it in lordosis, it must be expected that the lumbar fascia, the erector spinae muscles and the interspinous ligaments will become adaptively shortened. What happens then as a result of release of the fascial contracture of the leg is that the lordosis is lessened and all the shortened soft parts in the region of the lower part of the back are constantly stretched, pain is the result until the adaptive shortening is finally overcome.

According to my experience with chronic, long-standing disabilities referred to the lower part of the back it takes considerable time before pain and stiffness of the spine disappear after fascial division.

If it is proposed to fuse a lame back for the relief of symptoms and fascial contracture holds the lower portion of the spine in a deformed position, it would appear wise not to do the fusion or at least not to do it until some of the deformity has been corrected. The reason for so many failures following fusion may be this factor of deformity since the spine may be fixed in the position of discomfort. It would seem proper then to relieve deformity first and do the fusion later. In twelve cases reported in the questionnaire fusion had failed and a subsequent fasciotomy had given relief. There were fifteen failures when the fasciotomy had been done after a lumbosacral fusion.

CONCLUSIONS

- 1 Division of the fascia lata above the trochanter has a place in the treatment of troubles low in the back.
- 2 The operation should not be performed when there is x-ray evidence of abnormality of the spine.
- 3 The operation is indicated in cases of lame back and in cases of pain along the sciatic nerve if the normal lumbosacral angle is increased or decreased.
- 4 Contracted fasciae latae can exert abnormal pull on the pelvic bones and as a result disturb the mechanics of the whole spine.
- 5 Three hundred and fourteen patients were completely relieved as a result of fasciotomy.
- 6 With such a high percentage of good results the operation has a distinct place in the treatment of sciatic pain and pain low in the back in well selected cases.
- 7 Sciatic pain is not the prime indication for surgical operation on the fascia lata until pathological changes of the spine or the nerve have been ruled out.
- 8 Fasciotomy should not be done unless there is evidence by all the tests mentioned that the fascia lata shows contracture.
- 9 It is impossible to state definitely at present whether the mechanical distortion of the spine causes sciatic pain or whether this pain is due to pressure from spasm of the muscles about the posterior aspect on the hip joint.

234 Marlborough Street

ABSTRACT OF DISCUSSION

DR. ALAN DE F. SMITH, New York. Ninety-eight fasciotomies for sciatica have been performed at the New York Orthopaedic Hospital. A study of the results has been made of forty-nine patients operated on between October 1934 and February 1936 with an average follow up period of six months. In all, sixty-one operations were performed on nine extremities. In those cases in which a fasciotomy was performed uncomplicated by other operations, 75 per cent. showed excellent or good results. In twenty patients who had previous

sciatica after spine fusion, this symptom was relieved by fasciotomy in only 25 per cent. The latter group was composed of patients having pronounced abnormalities of the lumbosacral joints and in this respect differed from the first, in which the results were so much better. However, many of those classed as unsatisfactory obtained temporary relief lasting from two to sixteen months. In several other cases the reason for the failure could be traced to factors other than the operation. In all, twelve patients who had had low back pain, as distinguished from sciatica, had none after fasciotomy. Twenty obtained no relief from back pain, and four who had no back pain before fasciotomy did have it afterward. The operation, therefore, does not appear to be useful in cases of back pain aside from sciatica, since relief resulted in only 33 per cent and in some of these probably was attributable to spine fusion rather than to fasciotomy. It must be realized that sciatica is a symptom rather than a clinical entity and that it may be caused by a number of different conditions. That it can be relieved by fasciotomy in certain cases has been definitely proved. How to select those cases more certainly, it is now our task to determine. Until we have a better understanding of the mechanism by which fasciotomy relieves pain, this will be difficult. Dr. Ober says that he would not expect the operation to be successful in the presence of marked skeletal abnormalities at the lumbosacral junction. This, in the main, probably is true but I have had several brilliant successes by this operation in such cases, and my feeling now is that in a case in which there is such an abnormality but with sciatica as the only symptom I would try fasciotomy first, provided, of course, the fascia lata was tight, and would do a spine fusion only if that failed. I wish to emphasize, however, that I still believe that spine fusion has an important part to play in the group of cases caused by abnormalities of the lumbosacral junction, prominent among which are posterior displacements of the fifth lumbar vertebra. Little can be expected of fasciotomy in patients with much arthritis in the lumbar spine. It is incumbent on us to exclude spinal cord tumors and protrusion of the intervertebral disk as causes of sciatica and stress should be laid on the importance of a careful neurologic examination. If there is any doubt, a spinal puncture with manometric reading and estimation of the total protein should be made.

DR. FRANK D. DICKSON, Kansas City, Mo. For two years following Dr. Ober's first presentation, none of these operations were done in our clinic, but during that time we examined our cases rather carefully, and after months of observation we found that the abduction sign occurred in a very definite percentage of cases of low back disability and sciatic pain and that the Ely sign was rather consistently associated with a positive abduction sign. With this positive evidence of shortening of the fascia lata in mind, we commenced to do these operations, setting up as our criteria (1) that there should be positive objective evidence of low back disability, (2) definite abnormal alignment of the lumbar spine, usually lordosis, (3) a roentgenologically negative spine, and (4) a definitely positive abduction and Ely sign. Operations were done in cases meeting these mentioned criteria, and we were so well satisfied with our results that we have continued to do them. I have not the exact number of cases in which operation was performed as I did not expect to discuss this paper. We have operated on between thirty-five and forty patients, and our results have been satisfactory in 75 per cent of these. We have been so well satisfied that in two cases we have abandoned our own rules and have done fasciotomies on spines showing roentgenologic congenital abnormalities. In both of these cases there was unilateral sacralization of the first lumbar vertebra. In both there has been relief from all symptoms. The one is over a year old, and the other is some months, and both patients have to use their backs strenuously. There is one point in Dr. Ober's presentation that I should like to emphasize, and that is the importance of a thorough division of the intermuscular septums particularly of the sheath of the sartorius, where it is often necessary to divide the sheath completely. My present attitude toward the division of the fascia lata is this: I think Dr. Ober has offered a very effective addition to the armamentarium for treatment of low back disability. I believe, however, that the operation must be used with caution and restraint, and it must be remembered that it is not a cure all for all low back or sciatic difficulties.

DR. EDWIN W. RYERSON, Chicago. Again there is offered a solution for low back pain and sciatica. In the years in which I have been coming to these meetings I have seen many new procedures advised and adopted. What is the reason that it is so difficult to find out the pathologic conditions underlying low back pain and sciatica? Obviously these people don't die of low back pain and sciatica. No specimens are obtained nor any scientific evidence as to what is causing these troubles except in those few who are subjected to laminectomies and in whom the foramen of the fourth or fifth lumbar nerve is exposed, or who can be seen post mortem in rare instances after accidents or the results of intercurrent disease. We do not have a good pathologic scientific foundation for most of our work on the low back and the sciatic region. Dr. Ober's operation is the result of experience and not of pathologic investigation, and yet no one can disregard an operation which relieves 75 per cent of the sciatic and low back pains uncomplicated by other pathologic conditions. One should not perform this operation except under the indications which the author has prescribed. Obviously we all have seen many cases of contracture of the thigh dozens of patients with infantile paralysis have been operated on by all of us, either with Soutter's method or the Campbell method, and we have lengthened the structures that hold the thigh contracted, yet how many of those patients have had low back pain? I can't recall that any of my patients complained sufficiently of low back pain to make me want to operate on them for the relief of that pain. Patients with spondylolisthesis have a very exaggerated lordosis and I can't recall any of the very many on whom I have performed spine fusions who complained especially of sciatic pain. Pathologically scientific evidence is lacking as to just what is causing the sciatic pain in these cases under discussion and the scientific proof of the results after the operation is lacking. Is the pain in these cases due to a narrowing of the fifth lumbar foramen? We don't know. Is it due to irritation at the fifth or fourth lumbar foramen? We don't know. We are doing something which gives relief and it is perfectly proper to do so. I am not objecting in the least to it, but here we have an operation for the relief of a symptom the cause of which symptom we do not know, the result of the operative procedure which may or may not give relief we do not know. I should like to wait another year or two before I do any of these operations for the symptoms as presented by the author. Why are the fascia lata and these anterior structures contracted? We don't know. We know we used to walk on all fours and we know that a horse or a mule can't kick upward very far because he has a short set of structures that hold his thigh in more or less flexion. It may be a relic of prehistoric days when we walked on all fours.

DR. BECKETT HOWORTH, New York. I wish to record two observations in this problem which may be a bit unusual. Dr. Ober has mentioned the importance of the abduction and the straight leg raising signs and Dr. Smith has mentioned the observation that the former sign may be quite variable. Variations between different examiners in different hospitals are to be expected, but when the sign is tested by the same examiner in the same way on the same patient on different days often there is a distinct variation and this has been cause for wonder. Recently I did a fasciotomy on a woman of 35 who had had sciatica of six months' duration and also had a low back abnormality. I realized she might not be relieved. The type of low back abnormality is not pertinent to the point. She was relieved of what she called "tension" on the table the operation being done under a local anesthetic. She felt better for ten days or two weeks, all during this time the two signs having been negative, her leg dropping to about 15 degrees of adduction in the Ober test and her straight leg raising having increased from 30 degrees to 60 or 70 degrees. Suddenly she had an attack of sciatica again, a very acute severe attack and immediately thereafter the signs again became quite positive as positive as or more positive than they were in the first instance. The fascia the intermuscular septums and the sheath of the sartorius had all been divided and at no time was there any evidence of positiveness of the Ober sign until the sciatica recurred. I record this as an instance which may help in solving the puzzle of what causes the positiveness of the sign, although I realize that it might be due to contrac-

ture, to muscle spasm, or in some cases to both. The second instance concerns a little different problem, that of a dental student who was compelled in his school to run his dental engine with his foot. He had to work the pedal and he said that when he did his thigh was so uncomfortable that he couldn't do his hour's work and he was afraid he would have to drop out of the school. He had been seen by two or three orthopedists and they told him he had myositis. He had had all kinds of physical therapy for months without relief. A roentgenogram, which had not previously been taken, showed that he had a slightly displaced upper femoral epiphysis which had united. He also had a contraction of the fascia lata, observed several times. Because of this I did a fasciotomy and he noticed immediate relief of "tension" and the feeling of tightness in his thigh. After three weeks he went back to his dental school, finished the year and ran his machine without any difficulty.

DR G. E. HAGGART, Boston. In view of the belief that fasciotomy is not indicated in the presence of a pathologic condition of the bone, the following observations, in four cases of severe hypertrophic arthritis of the lumbar spine, are of interest. These particular patients were seen in the past year. In addition to extensive hypertrophic changes of the lumbar spine, all had marked sciatica as well as contracture of the fascia lata. A variety of medical treatments did not relieve the pain. It was therefore decided that fasciotomy should be performed, since the operation was relatively simple and would not prolong the patient's period of hospitalization. In each instance there was immediate pronounced relief of pain. One other case was of interest from a different standpoint. A 38 year old carpenter was first seen two years ago because of severe sciatica and low back pain. Examination revealed a marked unilateral contracture of the fascia lata. Operation was advised but refused. The patient returned a year and a half later at which time there was a definite contracture of the fascia on both sides. Again fasciotomy was advised. This time it was accepted. However, he was first submitted to lumbar puncture, as is our custom in all cases of sciatica. The total protein of the spinal fluid was elevated and therefore studies with iodized oil were performed, which revealed definite evidence of a herniated disk. This patient was then operated on by Dr. Poppen of the Neurosurgical Service, who found and removed a herniated disk between the fourth and fifth lumbar vertebrae. Within one week following operation the bilateral contracture of the fascia had diminished 60 per cent, while the sciatica had almost disappeared.

DR FRANK R. OBER, Boston. I should like to ask all men here who have had experience with fasciotomy to write me some time in the near future so that I may send them a questionnaire. The trouble about the operation is that it is too easy and may be a pitfall for those who are not careful in making a diagnosis. I am convinced of this because I have been told that there are many who have gone ahead and done a fasciotomy in the presence of sciatica without going into details about a patient's condition. The first patient was a young neurologist in New York. This was three years ago last May and he has had complete relief from symptoms ever since. Several years ago I was convinced that many patients with lumbar lordosis and low back pain without obvious changes in their spine by x-ray examination might possibly have some condition outside the spine causing the disability. I had already found out in severe cases of flexion contracture of the hip that there would be pain in the lower part of the back. In those cases in which there was paralysis of the gluteal muscles a transplantation was devised to aid the weakened gluteal muscles. It was noted that after this operation had been done on both sides a severe lumbar lordosis would disappear within a few weeks. It was also noted that in severe cases of sciatica the patients complained of a snapping hip. A snapping hip is due to a tight iliotibial band slipping back and forth over the trochanter. The test for snapping hip as shown by me is exactly the same as that which is now practiced in testing for contracted iliotibial bands. Dr. Dickson is to be commended for his remarks and also for the careful way he went about working up his cases. I see a great many patients with sciatica and lame back that I never

operate on. They get well without any fasciotomy. In the last three years there must have been ten backs that I have seen without operation to one case in which a fasciotomy has been done. Dr. Ryerson has discussed the question as a solution for all back troubles. That is far from the case. I simply want to add that contracted fascia lata has something to do with some of the low back conditions. It is just another monkey wrench thrown into these troubles. One of the reasons for the recurrence of the sciatic pain in some of these cases, as mentioned by Dr. Howorth, is that these patients have a healing wound and there is irritation of the muscles, especially the gluteus maximus.

CONGENITAL HYPERTROPHIC PYLORIC STENOSIS IN INFANCY

EDWARD J. DONOVAN, M.D.

NEW YORK

In a former paper on congenital hypertrophic pyloric stenosis published in 1932, I reported a series of 100 consecutive cases in which I had operated at the Babies Hospital, New York, with only one death. The purpose of this paper is to show the continued success of surgical treatment as evidenced by an additional 143 consecutive cases without a death. No important changes in the treatment have been made since my last report.

Congenital hypertrophic pyloric stenosis is one of the most interesting surgical conditions encountered in early infancy because, while it can be permanently and easily cured by the Fredet-Rammstedt operation after proper preparation, there are still several phases of the disease and its cure about which little is known. Why the tumor disappears after the age of 3 months or why it disappears after the circular muscle is cut has not yet been determined.

The various forms of medical treatment, such as the administration of atropine, thick feeding or refeeding after vomiting, have not been successful in my hands, and I continue to advocate surgical intervention as soon as the diagnosis is established, except in a few mild cases in patients who are nearly 3 months old. At its best, medical treatment is prolonged and uncertain and requires expert nursing, long hospitalization and the removal of the baby from the breast. Surgical treatment, on the other hand, is quick, certain, and permanent in its results and allows nursing to be resumed a few days after operation. From an economic standpoint alone, the advantages of surgical treatment are obvious.

The causation of pyloric stenosis has not been definitely determined, but perhaps the most plausible theory is that of developmental hyperplasia of congenital origin of the circular muscle of the pyloric ring. To support this theory, I mention that two 7 month premature infants at the Babies Hospital have had well developed tumors and that tumors have been felt many times shortly after birth. All authorities agree that the essential feature of the pathologic condition is hypertrophy of the circular muscle of the pylorus. The growth of the circular muscle, which may be so great as to occlude almost completely the lumen of the pylorus, forms the tumor that is characteristic of the disease. This tumor, which is usually about 2.5 cm. in length and of cartilaginous consistency, stops abruptly

Read before the Section on Surgery, General and Abdominal at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1937.

at the duodenal end but merges gradually with the stomach at the gastric end. Because of this almost complete obstruction, the stomach may be four or five times its normal size. It is the spasm of the pylorus accompanying this hypertrophy that causes the symptoms.

The symptoms may date from birth, but they usually start between the second and the fifth week, the average age being 3 weeks. Vomiting, which is always the first symptom, may start abruptly but ordinarily does not. It may follow each feeding and is almost always projectile, the food often being projected several feet. The quantity vomited is small at first but later increases. The vomitus never contains bile, which is an important point in the differentiation of this condition from duodenal obstruction. It may, however, contain blood. There is always gastric retention so that the amount vomited at one time may be considerably more than the previous feeding. As a result of this vomiting and loss of nourishment, the babies soon become dehydrated and, with the rapid loss of weight, they may become emaciated in a comparatively short time. For the same reasons their stools are usually small and dry and there is a marked decrease in the amount of urine voided.

If the abdomen is watched carefully after a feeding, visible gastric peristaltic waves may be seen in the epigastrium passing from left to right, often in rapid succession. These waves may vary considerably in size and are best seen when the stomach is partially filled. Waves were present in all cases of this series, and, while not pathognomonic of the condition, they are a help in establishing the diagnosis. In addition to the gastric waves, a pyloric tumor can always be felt. It is usually located to the right and above the umbilicus, and, while it varies considerably in size with the contractions of the pylorus, to feel it has been well compared to feeling a small olive. Writers disagree on the importance of locating the tumor, but I believe it is pathognomonic of this condition and may be felt in every case if a painstaking examination of the abdomen is made. It is not always possible to feel the tumor at the first examination, as the child is hypertonic and sufficient relaxation of the abdominal muscles may not be obtained at once. A sugar pacifier is generally sufficient to relax the baby after his stomach has been emptied with a small stomach tube. Sometimes the lineae transversae of the rectus muscle may be mistaken for a tumor if the abdomen is not well relaxed. I have often found it helpful to press the fundus of the stomach gently toward the right with the left hand while palpating for the tumor with the right hand. The tumor is always felt best when the stomach is empty, and it is easy to feel in infants who have lost considerable weight. Light anesthesia has been suggested for the abdominal examination, but I have not found it necessary.

Some authors see distinct advantages in using roentgenograms or the fluoroscope to make the diagnosis, even to the extent of differentiating by this method the cases in which an operation should be done from those in which medical treatment should be used. I have purposely avoided this method of diagnosis because I feel that it is possible to make the diagnosis by other means, having always obtained all the information desired, even to the amount of gastric retention, without it.

Preoperative preparation is perhaps the most important factor in lowering the operative mortality. Previous to my last 243 cases, it was customary to operate in the bad cases as an emergency measure. As

a group, they presented the poorest possible surgical risks, and the result was a very high mortality. At that time the mortality from collapse alone was reported in some series as high as 9 per cent. This high mortality is well illustrated by the fact that there were six deaths in nineteen cases at the Babies Hospital before the value of preoperative preparation was understood. I now feel that there is no need to hurry operation even though the child is vomiting everything. If the baby is in a particularly bad condition, he is given one or two preoperative transfusions by the Lindemann method, 20 cc of whole blood for each kilogram of body weight being used. Most of these babies have alkalosis, with a high concentration of serum carbon dioxide and a low concentration of blood chlorides, therefore all patients receive from one to four hypodermoclyses of 100 cc of physiologic solution of sodium chloride before operation. It is amazing how easily one may convert a particularly bad surgical risk into a fair one in two or three days by this means.

The Fredet-Rammstedt submucous pyloroplasty was used in every case. It has been found entirely satisfactory and gives a permanent result, as shown by the follow-up. It may be done in about fifteen or twenty minutes with no attempt made to hurry the operation. Ether by open cone was used in all but three cases (these three being done with procaine hydrochloride block because of the presence of an infection in the respiratory tract). Local anesthesia is contraindicated in the majority of cases, it prolongs the operating time and may interfere with the healing of the wound. There was one case of postoperative infection in the respiratory tract in this group. While the operation is mechanically simple, a few details are essential for its success. To maintain the body heat during operation, a hot water bottle is placed under the child on the operating table. Just before the abdominal incision is made, the stomach is emptied by passing a soft rubber catheter, size 18 F. The incision used is an upper right rectus incision about 4 cm long, 1 cm from the midline and high enough to overlie completely the right lobe of the liver. This not only makes closure of the abdomen easier but practically insures against postoperative rupture of the wound. When the abdomen is opened, the right lobe of the liver is retracted upward and the pylorus delivered into the wound. The tumor is held between the thumb and the index finger of the left hand. Beginning at the duodenal end, an incision is made over the entire extent of the tumor in its least vascular part and through the peritoneum and the superficial part only of the circular muscle. The cut edges of the muscle are then separated with a small mosquito forceps until the mucous membrane completely fills the incision. Any bleeding encountered can usually be controlled by application of hot moist pads. If not, the vessel is under-run with fine black silk. In some of the older cases separation of the cut edges may be more difficult and more bleeding may be encountered. If it cannot be stopped by these means a small strip of muscle from the rectus may be sutured in the pyloric incision. (This procedure was necessary in only two cases.) It is important to see that all bleeding is stopped before the abdomen is closed, because some deaths due to hemorrhage from pyloric incisions have been reported.

After the bleeding is stopped, the pylorus is dropped back and the abdomen closed in layers, continuous chromic catgut sutures being used for the parietal peritoneum and anterior rectus sheath, with Michiel

clips for the skin. A piece of gauze just large enough to cover the incision is strapped into place with adhesive plaster in order that any bleeding from the incision may be quickly detected. From the operating room the child is taken to a constant temperature room used exclusively for such patients. The head of the bed is lowered until he recovers from the anesthetic to prevent aspiration of mucus. Two hours after operation, 15 cc of water is given by mouth, and four hours after, the first feeding of 4 cc of breast milk and 4 cc of barley water is given. The breast milk and barley water are increased from 5 to 10 cc with each three hour feeding until the child is taking 30 cc at the end of forty-eight hours. The breast milk is then increased from 5 to 10 cc daily until the caloric requirements are met. One or two clyses of physiologic solution of sodium chloride or 3 per cent dextrose in such a solution are given each day for the first three days. All feedings for the first five days are given with the medicine dropper, and breast-fed babies are allowed to nurse once on the fifth day, twice on the sixth day, and so on until they are completely breast fed. If the baby is to be discharged on a formula, evaporated milk seems to be well tolerated, and, beginning about the seventh day, one formula feeding is substituted for a breast milk feeding until he is completely on the formula. These children have a low food tolerance because of their long period of starvation, and postoperative feeding must therefore be very carefully planned and an effort made to obtain breast milk for all patients for the first five days. With this routine, it is exceptional to have anything but a smooth convalescence, and 90 per cent of the patients in this series showed an appreciable gain in weight before being discharged from the hospital between the tenth and the fourteenth day after operation.

The complication most to be dreaded is accidental opening of the duodenum. The change from thick pyloric tumor to thin duodenum is rather abrupt, and great care must be exercised in separating the cut edges of the muscle toward the duodenal end. This complication did not occur in this series. There was no bleeding either from the pylorus or from the abdominal incision. There have been no postoperative hernias to date and only one case of postoperative pneumonia. The course of 92 per cent of the patients has been followed, and in no case has the result not been entirely satisfactory.

SUMMARY

1 Congenital hypertrophic pyloric stenosis occurs about seven times more often in boys than in girls. In the group reported on there were seventeen girls and 126 boys.

2 Vomiting is always the first symptom and in the majority of the cases begins between the second and the fifth week of life.

3 The tumor, caused by hypertrophy of the circular muscle of the pylorus, is pathognomonic of the condition and may be felt in every case.

4 The Fredet-Rammstedt submucous pyloroplasty is the most satisfactory operation and gives a permanent result, as shown by the follow-up of the cases reported.

5 There were no deaths in this group. One death occurred in a group of 100 cases reported in 1932, making a total of one death in the last 243 cases.

6 Preoperative preparation is the greatest factor in bringing the mortality to its present level.

424 Park Avenue

ABSTRACT OF DISCUSSION

DR WILLIAM E LADD, Boston. Dr Donovan should be congratulated on the results achieved in his series of cases of congenital hypertrophic pyloric stenosis. It is interesting that two clinics running entirely independently of each other should have arrived at identical conclusions. The only differences in our methods are minor ones. Since 1915 at the Children's Hospital in Boston, 635 patients suffering from congenital hypertrophic pyloric stenosis have been treated in the surgical wards. In this series thirty-four died, giving a mortality of 5.4 per cent. The greater number of these deaths occurred in the earlier years when our care of infants was less advanced, and when we treated these patients as emergency cases without adequate preoperative care. From 1930 to 1934 there were 160 consecutive operations performed for pyloric stenosis without a fatality. In 1935 several deaths occurred, but since Jan. 1, 1936, there have been fifty additional patients operated on without a death. I am in accord with Dr Donovan on the time selected for operation, with his preoperative preparation, and with his choice of ether as an anesthetic. Our operative technique is identical with his, except for the suture material used for closure. In the early part of our series, catgut was used but recently fine silk has been satisfactorily substituted in its place. The reason for this change is that in these emaciated infants with almost no subcutaneous fat the catgut knot occasionally gathered serum around it, and it would extrude through the incision. This is less likely to occur with silk. Our postoperative care, in general, is similar to Dr Donovan's. Instead of using breast milk and barley water, we use whey for the first twelve hours, then breast milk and whey for twenty-four hours, and gradually supplant the whey by breast milk at succeeding feedings. In our regimen, at the end of seventy-two hours the infant's feeding has been increased to meet his caloric requirements. In reviewing the deaths in our series, it is apparent that the majority were in the early years of the series and were due to inadequate preoperative preparation. There were, however, three deaths from hemorrhage which I consider inexcusable. There were also three deaths following failure of the wound to heal and evisceration without evidence of infection. A possible reason for this unfortunate occurrence is the presence of asymptomatic scurvy, which my associate Dr T H Lanman has found to be common in ill nourished infants. Vitamin C deficiency carries with it delayed and weak wound healing. We have therefore in recent months given all these infants prophylactic doses of cevitamic acid and we hope this may prevent any future difficulties with wound healing.

DR ALFRED JEROME BROWN, Omaha. In the preoperative diagnosis I believe that the use of barium sulfate and the x rays is unnecessary. The diagnosis can be made without them. Furthermore, I would prefer that the baby's first meal after the lumen of the pylorus has been restored be either mother's milk or a modification of milk prescribed by a pediatrician rather than a mixture of residual barium. No matter how carefully the stomach may be washed out after the x-ray examination, some barium will remain in the stomach, to pass through after operation. Operation for congenital hypertrophic pyloric stenosis is not an emergency, for the most pressing indication is to see that these children are given fluids to restore water balance before any surgical procedure is undertaken. The method of restoring fluids which I use is intraperitoneal injection of salt solution, which is quickly and simply done. It has not increased the difficulty of the operation nor has it resulted in infection in any of my cases. General anesthesia, preferably ether by the drop method, is the anesthesia of choice in these cases. The operation is short, rarely lasting over ten or fifteen minutes, and can be done under primary anesthesia. I have had no postoperative complications in any of my cases that can be ascribed to general anesthesia. I have operated with the patient under local anesthesia but have been more worried after local than after general anesthesia. There is always the danger of an infant crying suddenly and increasing the intra-abdominal pressure, with the possibility of evisceration. Another factor against local anesthesia is the amount of drug used. It is difficult to obtain proper anesthesia of a sufficient area of the abdominal wall to make a 1 or 1½ inch incision without using at least 10 cc, or 2½ teaspoonful of

fluid If a 1 per cent solution of procaine hydrochloride is used, there is 10 mg of procaine in each cubic centimeter of solution If 10 cc is used, this will make a total amount of the drug of 100 mg, which equals 0.1 Gm, or $1\frac{1}{2}$ grains The lethal dose of procaine is from 40 to 50 mg of the drug per kilogram of body weight A kilogram is $2\frac{1}{4}$ pounds Consequently, if 10 cc of a 1 per cent procaine solution is used, 100 mg of procaine is given, and this for a child of 5 pounds weight is equal to the lethal dose of the drug injected intravenously, and most of these infants weigh but a little over 5 pounds It is true that from the subcutaneous tissue the procaine is absorbed much less rapidly than when injected intravenously, otherwise, all these children would be in serious danger But, in the use of local anesthesia, these infants are subjected to a real danger of procaine poisoning

DR JOHN J. GILBRIDE, Philadelphia Congenital hypertrophic pyloric stenosis is not common The diagnosis is usually made comparatively late, because the disease frequently pursues a rapid course and terminates fatally within four or five weeks in genuine cases Vomiting is the first symptom, but vomiting is always common in young babies, and unless it becomes severe and persistent it is often not regarded seriously The first case of this type that came under my observation was in about 1909, and I published a report of it Large series of cases were reported by others soon afterward in the literature, and claims were made for their cure under medical treatment, but these claims, I believe, can be discounted Surgical operation does save some cases of pyloric stenosis of a lesser degree of severity, but most of the patients with complete pyloric obstruction die early from starvation or from aspiration pneumonia as the result of the severe vomiting

DR ALFRED A. STRAUSS, Chicago I fully agree with the essayist on the points that he has brought out I have had a similar experience I have done 431 operations in these cases since 1915, with a mortality of a little less than 2 per cent Since 1924 I have had no mortality in a series of 167 cases The earlier mortality was similar to that which Dr Ladd described and was due to the poor preparation of the patients In other words, they were being operated on before they were properly prepared with fluids, dextrose and blood transfusions I will add that occasionally in some of the cases, possibly, blood transfusion is necessary after the operation I differ with Dr Donovan in only one respect, and that is in the operating technic I describe the pylorus using the musculature of the stomach, using the free edge of the attached omentum to protect this area from leakage and hemorrhage It is true that Ladd and Donovan and these men can do this operation without mortality, but what about the general surgeon who does one in a year, or three in two years, or five in three years? He will report that he has lost one out of five from hemorrhage or a pinpoint perforation Therefore a much safer procedure and one that takes little effort, is to suture the free edge of the attached omentum over the split muscularis, which will first, prevent bleeding, and, second, prevent a pinpoint leakage, which often leads to fatal peritonitis I make this plea for the men who do not have so much material to work on

DR MISCH CASPER, Louisville, Ky Considering the large number of case reports, I wonder whether in the larger cities, where better pediatricians are available, the diagnosis is made more often than in districts where there is a large country practice My experience differs from that of one of the speakers on anesthetics I think that ether is more dangerous than possible procaine poisoning in such cases My custom is to give procaine and just a whiff of chloroform, not for the physiologic effect of the latter but just enough to keep the baby from crying and interfering with the surgeon's work I have had no mortality from the anesthesia I wish to emphasize the point made by the last speaker on covering the wound with omentum That is a splendid point in the technic Recently I had occasion to reopen the abdomen of such a patient operated on about a year ago, the second operation being a strangulated hernia, having no relation to the first When I inspected the site of the old operation I found that the effects of the operation had almost entirely vanished, there being no evidence of the former condition, tumor or anything else, and the patient had made a good recovery

HUMAN AUTONOMIC PHARMACOLOGY

IV THE USE OF ACETYL-BETA-METHYL CHOLINE CHLORIDE (MECHOLYL) AS A DIAGNOSTIC TEST FOR POISONING BY THE ATROPINE SERIES OF DRUGS

WILLIAM DAMESHEK, MD

AND

OSCAR FEINSILVER, MD

BOSTON

We have recently had the opportunity of observing five cases with brief psychotic episodes following administration of from three to six drops of a medication prescribed for mydriasis The first patient, a medical student in our laboratory, presented a diagnostic problem on her admission Although the diagnosis of atropine poisoning with psychosis was finally considered, it was at first thought that the patient might have dementia praecox or an acute manic-depressive episode The use of acetyl-beta-methyl choline chloride (mecholy, Merck), suggested itself as a diagnostic test for possible atropinism, since in our experimental work¹ it had been shown that even a very small dose of atropine ($\frac{1}{100}$ grain, or 0.00065 Gm) was sufficient to cause complete inhibition of most of the effects of mecholy, even when the latter drug was given later in large dosage (from 25 to 50 mg) Thus the complete absence of the characteristic mecholy effects (sweating, rhinorrhea, salivation, lacrimation) when the drug was given in a dosage of 20 mg served to confirm the final clinical impression of atropinism When the patient's psychosis had subsided, reinjection of mecholy was followed by the typical effects of the drug Within a relatively short period after this first patient was studied, four other cases with the same type of psychosis appeared at the hospital The same tests performed in these cases gave similar results We feel that the data obtained in these cases are sufficiently important from both diagnostic and prognostic standpoints to warrant reporting It was later discovered that the drug responsible for these unusual psychotic episodes following administration into the conjunctival sac was neither homatropine nor atropine but scopalamine, one of the atropine series

REPORT OF CASES

CASE 1—A woman, aged 24, a medical student, was brought to the hospital after having been found wandering about the streets for several hours in a dazed condition On admission to the hospital she was exceedingly "jumpy" and apparently frightened Repeated questioning elicited only an occasional response, and replies, when obtained, were for the most part irrelevant and incoherent Spontaneous speech was considerably disjointed She appeared emotionally inert, although an occasional smile was seen which was not elicited by any apparent external stimulus Although no auditory hallucinations were elicited, there were many visual hallucinations and she talked a good deal of seeing various types of animals cotton-fields and other completely unrelated objects The sensorium was considerably clouded She was obviously disoriented as to time and person, although she appeared to know her sur-

The tongue appeared unusually dry. The heart rate was rapid, and there was reduplication of both the first and second sounds. The blood pressure was 138 systolic, 100 diastolic. The reflexes were equal on the two sides but were markedly hyperactive. The abdominal reflexes were absent. The urine showed no albumin or sugar and the sediment was negative. The

apparently homatropine. Repeated questioning finally disclosed that she was to have had refraction of the eyes that morning and had instilled several drops of the medication into the conjunctivae. Memory following this was blank.

It was felt by some observers that, although the paralysis of the pupillary reflexes was probably a homatropine effect, the

psychosis could not adequately be explained in the same manner. On the other hand it was reasoned that, if the psychosis was due to central absorption of one of the atropine series, the presence of atropine in the body in concentration however small would prevent the characteristic effects of mechohyl. In a large series of experiments in the Research Laboratory of the Boston State Hospital, the strikingly uniform effects of the latter drug had been demonstrated: within thirty seconds there was always marked rise in pulse rate with concomitant slight to moderate drop in blood pressure, within one minute there was a marked flush of the face and upper portion of the trunk,

patient was either allergic to homatropine or had mistakenly been given atropine. Six hours after admission to the hospital the psychotic symptoms began to clear rapidly, and nine hours after admission the mental status was completely normal. The following morning, twenty-four hours after admission, mechohyl was again administered in the same dosage of 20 mg. On this occasion the pulse rate rose from 90 to 120 per minute within thirty seconds and the blood pressure dropped from 130/80 to 86/64. Extreme flushing of the face and upper half of the body, lacrimation, salivation, rhinorrhea and drenching per-

together with lacrimation, rhinorrhea and salivation, perspiration, usually drenching in type, then occurred. This reaction could readily be terminated by the injection of a small dose of atropine sulfate, conversely, if a small dose of atropine (or scopolamine) was previously injected, the full mechohyl reaction failed to develop, although there might be slight flush and slight increase in pulse rate. The patient was accordingly given a subcutaneous injection of 20 mg of mechohyl. Absolutely no sweating, lacrimation, salivation or rhinorrhea occurred, although the pulse rate rose from 100 to 120 per minute and a slight flushing of the upper part of the body occurred. This almost complete lack of reaction to mechohyl was considered presumptive evidence of the presence of an atropine compound within the body. The diagnosis of acute atropinism with psychosis was therefore made and a favorable prognosis given. It was believed that the

spiration then followed in rapid succession. The patient complained of a sensation of tightness subternally. It was now apparent that the effects of the atropinism had completely disappeared and on the following day the patient was discharged well, although the pupils still remained moderately dilated. She has been well for six months and suffered no after-effects of her experience. Within the next few days, four more patients with an almost identical psychotic state presented themselves. In each instance drops, supposedly homatropine, had been instilled in the eyes for mydriasis prior to refraction. In a few minutes the patients felt queer and then became psychotic. Diagnosis was now readily made, but it was decided to utilize the diagnostic test with mechohyl further. Accordingly, mechohyl was administered in each case. For the sake of brevity, the results are presented in abstract. Patient 2, a boy aged 9, presented the

most severe psychosis Twenty-four hours after use of the drops he was still irritable and pugnacious and had a few visual hallucinations, in forty-eight hours he became mentally clear The first injection of mecholyl caused no effects, the second (at twenty-four hours) produced a slight reaction, the third (at forty-eight hours) caused the typical reaction Patient 3, twenty-four hours after use of the mydriatic, was still somewhat facetious and voluble, she showed a slight to moderate mecholyl reaction Patients 4 and 5, with mild psychotic episodes, apparently already diminishing at the time of entrance to the hospital, showed slight reactions to mecholyl at its first administration All patients showed complete clearance of their psychosis within six to forty-eight hours after the drops were instilled into the eyes, at which time the response to mecholyl injection was maximal

COMMENT

Pharmacologic and chemical tests of the preparation that was prescribed as homatropine in 1 per cent solution have resulted in identification of the drug as a 1 per cent solution of scopolamine hydrobromide From three to four drops were instilled by each patient into the conjunctival sac of each eye The amount of drug introduced in this manner was thus between 2 and 3 mg ($\frac{1}{30}$ - $\frac{1}{20}$ grain) Since much or the greater part of each drop must have been immediately lost by overflow, the exact amount of the drug remaining for absorption could not be determined, although this must have been small Constitutional reactions resulting from homatropine instillation into the eyes have been described but they are exceedingly rare² The psychosis resembled more closely that produced by scopolamine or atropine,³ although since all these drugs are closely related it is impossible to make any absolute clinical differentiation between their effects Absorption must have taken place by way of the mucosa lining the nasolacrimal duct and the nasal mucosa The fact that psychosis occurred in every instance and was accompanied by only slight constitutional reactions makes one speculate regarding absorption of the drug along the olfactory nerve endings and thus directly to the brain Scopolamine psychosis is not rare, even when the ordinary very small doses ($\frac{1}{200}$ - $\frac{1}{100}$ grain, or 0.0003-0.0006 Gm) for sedative purposes are used Doses of 0.002-0.003 Gm ($\frac{1}{30}$ - $\frac{1}{20}$ grain) even though much was lost, were undoubtedly excessive for the children, the adult medical student (patient 1) has the weight and build of a 12 year old child

Scopolamine, atropine, hyoscyamine and stramonium are drugs which belong to the atropine series and as such have their most striking effects on the parasympathetic nervous system, on which they cause blocking ("paralysis") of the acetylcholine effect on the nerve endings In the presence of small amounts of atropine or scopolamine, the characteristic and strikingly constant effects of mecholyl are almost without exception abolished¹ Mecholyl is otherwise the most active drug that has been introduced into pharmacology in recent years⁴ Not only are its effects so striking but their constancy and predictability from patient to patient are even more noteworthy Thus, the absence of a mecholyl reaction in a given patient may be taken as presumptive evidence of the presence of one of the

atropine series As far as we know, no other drugs than those of this group have this inhibiting effect on the action of acetylcholine and mecholyl Mecholyl may thus be utilized as a clinical diagnostic test for the presence of an atropine drug within the body Its diagnostic value in our first case was of great importance

Not only may the "mecholyl test" be used as a diagnostic procedure, but it has some prognostic value as well The degree of psychosis (and presumably of the amount of atropine within the body) was found to correlate very closely with the degree of reaction to mecholyl With the psychosis in full bloom there was no reaction whatever to mecholyl, with lessening in the psychosis, a slight to moderate reaction to mecholyl followed, when the psychosis had terminated, the complete mecholyl reaction occurred

CONCLUSION

In the presence of a very small amount of one of the drugs of the atropine series within the body, acetyl-beta-methyl choline (mecholyl) fails to cause its characteristic effects of perspiration, salivation, lacrimation and rhinorrhea Thus mecholyl may be used as a diagnostic test for poisoning created by any one of the atropine series of drugs In a series of five cases of psychosis following the use of scopolamine, the test proved of distinct diagnostic and prognostic value

GONADOTROPIC SUBSTANCE IN THE
TREATMENT OF ACNE

GRACE E WILLIAMS, M D
AND

RUBEN NOMLAND, M D

Medical Adviser to Women and Professor of Dermatology Respectively
State University of Iowa College of Medicine

IOWA CITY

The existence of a probable endocrine dysfunction in acne has been assumed for many years The exact nature of this dysfunction and the identification of the specific factor responsible is still a matter of research and experimentation Clinical trial of the gonadotropic factor from pregnancy urine has given variable results according to several recent reports In none of these series were controls run to compare the improvement in patients not receiving the gonadotropic preparation

To determine the effectiveness of gonadotropic substance from pregnancy urine (antuitrin-S) in the treatment of acne, thirty-nine students were studied These all received the same local treatment but half were given gonadotropic substance and the half used as a control received injections of sterile water

Lawrence¹ reported favorably on the use of gonadotropic substance from pregnancy urine in a study of two series of acne patients In his opinion the gonadotropic mechanism was probably the one involved in an endocrine imbalance existing in acne patients

Rosenthal² reported a series of cases in which slight improvement of acne followed administration of a

gonadotropic preparation. He thought that it justified the belief that some abnormality of the pituitary-like sex hormone was associated with the development of acne.

McCarthy and Hunter³ were less optimistic after a study of a larger series of cases in which gonadotropic substance of pregnancy urine was used. They demonstrated a dysfunction of either the pituitary gland or the gonads in 41 per cent of the males and in 78 per cent of the females by means of the hormone tests of blood and urine. Although an endocrine imbalance was shown, the administration of gonadotropic substance to these patients failed to bring about improvement any greater than that obtained by other methods.

With this equivocal evidence in mind of a deficiency of sex hormone in acne patients, and in view of the variable degrees of improvement reported by others, we studied a group of thirty-nine college students. They were 19 years of age on an average and included twenty-eight women and eleven men. Eleven of these had severe, twenty had moderately severe and eight had mild acne. One student had received roentgen irradiation for two years previously without benefit.

Although a relationship seems to exist between endocrine imbalance and the acne of adolescence, we felt that local conservative therapy and faithful meticulous attention to details in the care and treatment of the skin was of greatest importance. With few exceptions the instructions for local therapy were as follows: Stop all picking or squeezing, discontinue the use of all cosmetic creams, wash with soap and water twice daily, keeping the skin nongreasy almost to the point of scaling, eat a diet low in carbohydrates and eliminate candy entirely, remove comedones as directed, apply the prescribed lotion two or three times a day, avoid iodized salt and shampoo the hair twice a week. The lotions were a drying lotion of the following formula: sodium bichlorate 10, starch 15, zinc oxide 15, lime water 120 and rose water to make 240, often alternated with lotio alba, made up of sulfated potash 4, zinc sulfate 4, and water to make 120. Comedones were removed by placing hot towels on the face for five minutes, then applying a thin coating of 3 per cent resorcinol in cold cream to the face and again applying hot towels for five minutes. The blackheads were then squeezed out with a comedone remover, the face rinsed with cold water and hamamelis water applied.

All thirty-nine patients were given these directions for local treatment. Half were given injections of gonadotropic substance, while the remainder were given injections of sterile water. The local treatment was directed by the department of dermatology and syphilology and progress notes were made there without knowledge of which patients were getting gonadotropic substance and which were getting water. The individual dosage was 2 cc intramuscularly three times a week, over a period of from eight to eleven weeks. The average dose was 5,700 rat units, the minimum dose 4,800 rat units and the maximum dose 6,600 rat units. The controls were given injections of sterile water according to the same schedule, so that the psychologic effect of the injections was the same.

There were no local reactions to the injections at any time, and in the women there was no effect on normal menstruation even though the injections were given during the menstrual period. The irregular menstrual periods of six became practically regular while receiving

the injections of gonadotropic substance from pregnancy urine, but four in the control group also became regular. Two of those receiving gonadotropic substance were also taking thyroid extract because of a low basal metabolic rate.

The progress of these patients was followed over a period of from four to six months after the beginning of treatment and the last observation was made from five to sixteen weeks after the cessation of injections. In about half of the cases it has been twelve weeks since the course of gonadotropic substance and the control injections were ended. All these patients continued the same local care and treatment of their skin.

The accompanying table indicates the response to treatment.

There was a slightly greater degree of improvement observed in the women over that observed in the men, but the difference was not striking. It is difficult to tell whether this might have been due to greater effectiveness of the pituitary-like hormone in the women or to their more faithful following of the instructions given for the local therapy. A comparison of the control group of women and those given injections of gonado-

Response to Treatment

	Total		Gonadotropic Substance		Controls	
	Num ber	Per Cent	Num ber	Per Cent	Num ber	Per Cent
Great	19	49	10	50	9	47
Moderate	13	33	7	35	6	32
Slight or none	7	18	3	15	4	21
	39		20		19	

tropic substance from pregnancy urine would lead one to believe that the latter was the explanation of this difference.

COMMENT

Of the thirty-nine cases of acne vulgaris treated in this series, 85 per cent of those given gonadotropic substance from pregnancy urine showed moderate to marked improvement, while 78 per cent of the control group given sterile water showed the same degree of improvement.

Although menstrual periods became more regular in nearly all the women given gonadotropic substance, they also became more regular in more than half of the patients of the control group. We could not find a correspondingly uniform improvement in the condition of the skin of those whose menstrual periods became regular. There were individual cases in which improvement of the skin paralleled the change from an irregular menstrual cycle to a regular cycle, but there were also individual cases in which this did not occur. The series was not large enough to justify any definite conclusion in this regard.

CONCLUSION

Our observations on thirty-nine students with acne lead us to believe that a deficiency of the pituitary-like hormone is not an important etiologic factor in acne. The results show a slightly greater degree (7 per cent) of improvement in the acne of the group treated with gonadotropic substance from pregnancy urine compared with the control group. The difference is hardly sufficient, however, to justify the expense and effort of intramuscular administration of the gonadotropic preparation. It would seem that local therapy is the most important factor in the management of acne.

STUDIES WITH HUMAN INFLUENZA
VIRUS

DURING THE INFLUENZA EPIDEMIC OF 1936 1937

THOMAS FRANCIS JR, MD

T P MAGILL, MD

M DOROTHY BECK, MA

AND

E R RICKARD, MD

NEW YORK

While the theory that a filtrable virus is the etiologic agent of epidemic influenza had been repeatedly expressed, no convincing evidence had been adduced to support the thesis until the recent studies initiated by the observations of Smith, Andrewes and Laidlaw.¹ These investigators reported in 1933 that ferrets were susceptible to infection with a filtrable virus present in the nasopharyngeal washings of patients suffering from epidemic influenza. Since that time strains of the same virus have been isolated in different parts of the world, and in each instance the recovery of virus has been associated with an epidemic of influenza. In addition, it was found that antibodies capable of neutralizing the infectious agent were present in the serum of human beings, most marked in those who had recovered from recent attacks of the disease. Furthermore, it was our opportunity to observe in 1934 the actual development of antibodies to the virus in three patients during recovery from influenza. These data constitute the evidence for considering the virus to be the primary causative agent of epidemic influenza.² The recent outbreak of epidemic influenza afforded an opportunity to study these points of evidence in greater detail and more accurately to evaluate their significance in relation to the disease.

CLINICAL CHARACTERISTICS OF THE EPIDEMIC
DISEASE

Epidemiologically and clinically the epidemic of influenza of December 1936-January 1937 in New York City presented no apparent differences from similar outbreaks which have occurred repeatedly since 1918. The epidemic appeared suddenly, spread rapidly and subsided spontaneously. Clinically, the onset was usually abrupt and the outstanding symptoms were chills, fever, generalized aches, prostration, nasopharyngeal irritation and a persistent dry cough. Coryza, if present, was of brief duration and mild. Apart from the irritation of the upper part of the respiratory tract, the physical examination revealed nothing noteworthy except relative bradycardia. The throat was edematous and somewhat glazed, and numerous red, dewy, swollen lymphoid follicles were seen on the pharyngeal wall and frequently on the soft palate. The leukocyte count was usually reduced below the normal level, in the present series it averaged 5,700. Fever commonly subsided on the third or fourth day. In fact, there was a surprising uniformity in the complaints and clinical course of most of the patients, and among the cases actually observed complications were extremely unusual. Bacterial studies revealed no con-

sistent results, Pfeiffer's bacillus was not prominent. In the latter part of December a rapid increase in the incidence of pneumonia occurred. While statistics are not available, the impression was gained in services where large numbers of patients were seen that the two diseases were coincidental and that pneumonia developed secondarily in very few of the patients who had epidemic influenza when admitted.

THE PLAN OF STUDY

Because other epidemic diseases of a mild nature have been confused clinically with epidemic influenza it was extremely important to establish if possible criteria which could serve as a basis for differential diagnosis. For this purpose, in addition to clinical observation, attempts were made to demonstrate the presence of virus in the upper part of the respiratory tract. To ascertain whether the illness was associated with the virus of human influenza, throat washings were obtained from the patient and inoculated into the nostrils of a ferret. Since facilities for maintaining ferrets under isolation precautions were limited, it was necessary to store some of the specimens of throat washings in a frozen state at -80°C before testing them. Either the test ferret was killed and serial passages made in additional ferrets, so as finally to permit identification of the filtrable agent, or the animal was kept for sufficient time to permit the development of immunity. In the latter case blood was taken and the serum of the ferret tested for its capacity to neutralize known human influenza virus. The presence of protective antibodies in the ferret's serum was interpreted to mean that the immune substances had developed as a result of infection by virus present in the patient's throat washings. Negative results meant that virus was not present in the material used. Certain specimens of throat washings were also introduced into mice in attempts to isolate virus directly in these animals without intermediate ferret passage.

Furthermore, serum was collected in the acute stage of illness and again from three to four weeks later so that the development of circulating antibodies to human influenza virus might be studied. Comparative titrations of neutralizing antibodies in the patient's acute and convalescent serum were made by the mouse protection test, different dilutions of serum and a constant amount (1,000 lethal doses) of virus being used. The test was terminated on the tenth day after inoculation, and the titer of the serum was considered to be that dilution which enabled 50 per cent of the test mice to survive. Parallel titrations of serum antibodies were made by means of the complement fixation test, a modification of the procedure described by Fairbrother and Hoyle³ being followed, with a saline suspension of infected mouse lung as antigen.

The results to be recorded comprise only a representative part of the complete studies conducted during the epidemic period. The present report deals primarily with the observations on a group of twenty-eight patients in one institution,⁴ together with those in four other cases that illustrate certain variables of interest.

DEMONSTRATION OF VIRUS

In this institution a group of twenty-eight patients, from 19 to 36 years of age, were seen in January 1937. From twenty-six, throat washings were obtained by

⁴ Dr Marian Tyndall of the New York Hospital cooperated by making these cases available for study.

having them gargle with meat infusion broth Individual ferrets were inoculated with each sample Specimens of blood were taken early in the acute illness and again three weeks later for comparative antibody titrations In twenty-four of the twenty-eight cases a final diagnosis of epidemic influenza based on clinical and laboratory evidence was made, in three, acute hemolytic streptococcus tonsillitis was observed One was a case of afebrile recurrent sinusitis No pulmonary complications occurred in any of the group In table 1 the results of studies on these patients are summarized Virus was shown by inoculation of ferrets to be present in eighteen, or 81 per cent, of twenty-two throat washings obtained in the twenty-four cases of epidemic influenza The high incidence of positive results is extremely striking and emphasizes the relative ease with which the presence of virus may be detected Since a fair number of

it was necessary to make simultaneous tests with the convalescent serum and with serum taken from the same subject during the acute stage of the illness

In the accompanying chart the record of one patient is presented graphically to illustrate the clinical course of the disease in relation to the presence of virus in the respiratory tract and the development of neutralizing antibodies in the blood Virus was obtained from the patient's throat on the first, second and fourth days of illness On the seventh day, seventy-two hours after subsidence of the fever, virus was present in only small amounts in the throat washings, as evidenced by the fact that the ferret receiving this material exhibited fever only after a delayed incubation period of five days Neutralizing antibodies which were present in the patient's serum in low concentration during the acute stage of the illness rose abruptly on the seventh day and had reached their height by the fourteenth

TABLE 1—Summary of Studies on Twenty-Eight Patients During Influenza Epidemic, January 1937

Diagnosis	Number	Past History			Average Day of Disease	Average Maximum Temperature	Average White Blood Cells in 1000	Virus in Throat Washings			Antibody Titer			
		Nega tive	1918 Posi tive	Other Posi tive				Posi tive	Nega tive	Test Not Done	Neutralization Test		Complement Fixation	
											Acute	Convalescent	Acute	Convalescent
Epidemic influenza	24	15	7	2	2.6	101.6	5.7 (8.5-3.3)	18	4	2	26 (0-200)	210 (15-640)	11 (0-32)	119 (8-512)
Hemolytic streptococcus tonsillitis	3	3	0	0	2.6	101.5	16.5	0	3	0	63 0	60 0	24 0	24 0
Recurrent sinusitis	1	1	0	0	5.0	98.0	4.8	0	1	0	0	0	0	0

Numbers in parentheses represent the range of variation The antibody titers are expressed in terms of the final dilution of serum

the samples had been maintained in storage for from one to two months before testing, the significance of the results is heightened

Moreover, after the single observation already recorded of direct transmission of the disease from man to mice,⁵ five samples of throat washings from these patients were instilled into the nostrils of mice Virus was isolated directly in mice from three of the five specimens tested Little or no evidence of infection was observed in the mice during the first three passages, but in mice of the fourth serial passage early lesions were seen in the lungs Thereafter a rapid enhancement of virulence occurred

The virus recovered from the throat washings of all these patients was shown immunologically to be the human influenza virus It was neutralized by serum of animals known to be immune to human influenza virus Furthermore, the serum of animals recovered from infection with the newly isolated strains of virus possessed the capacity to protect mice against older established strains of human influenza virus but not against swine influenza virus The actual recovery of human influenza virus in the great proportion of the cases of this series indicates the close association of that virus to the epidemic disease

On the other hand, no virus was recovered in the three cases of hemolytic streptococcus infection or in the one case of afebrile recurrent sinusitis which were included in the group (table 1 and cases 52 and 53 in table 3)

DETERMINATION OF CIRCULATING ANTIBODIES TO THE VIRUS

Since a comparatively high proportion of adult serum contains some antibody to human influenza virus, to evaluate the antibody content of the convalescent serum

day Thereafter, a gradual decline began The observations in this instance appear to typify the general results and suggest, furthermore, that the time of disappearance of virus from the throat tends to coincide with the onrush of antibodies in the blood

Considerable variation occurred in the titers of the acute serums as measured by the mouse protection test

Recovery of virus and development of antibodies in the course of influenza

for neutralizing antibodies The average titer of the acute serums was 1 26, and although the titer in the case of sixteen of the twenty-four patients with influenza was 1 15 or less, in two instances titers of 1 100 and 1 200, respectively, were noted Nevertheless, comparative tests with the convalescent serums revealed that in each instance after recovery from epidemic influenza a sharp rise in the neutralizing antibodies had occurred In comparison with an average titer of 1 26 for the acute serum, the average titer of the con-

5 Francis Thomas Jr and Magill T P Direct Transmission of Human Influenza Virus to Mice Proc Soc Exper Biol & Med 36: 132 (March) 1937

valescent serum was 1 210, with a variation of from 1 15 to 1 640, and while the titers of the majority of the acute serums were 1 15 or less, the titers of all but one of the convalescent serums were higher than 1 15

Parallel titrations of antibodies in the same serum as measured by the complement fixation test gave similar results. The complement fixation titers of the acute serums varied from 0 to 32, with an average of 11. The average titer of the convalescent serums was 119. The titer of all but three of them was greater than 32, with fourteen having titers of 128 or more. In table 2 are presented individual cases that illustrate variations in the serologic reactions observed in proved instances of the epidemic disease. Thus it is seen that the marked rise in antibody titer during convalescence from epidemic influenza is observed not only with the neutralization test but with the complement fixation

VARIATIONS IN THE CLINICAL PICTURE

With these procedures as a basis it becomes possible to elicit information regarding the variability in the clinical picture exhibited by different patients during an epidemic period. A few examples are cited to illustrate these features. One person after heavy exposure was found to be harboring influenza virus in the throat although no evidence of infection presented itself. In another proved case (case 79, table 2) there were minimal symptoms of twenty-four hours' duration, with a normal leukocyte level and a temperature of 99 F six hours after throat washings had been obtained. Both these persons, who later showed an increase of antibodies in the serum, might well be considered to represent carrier states or subclinical infections. In another instance virus was obtained from the throat washings of a healthy exposed person who twenty-four hours later became ill with a typical attack.

test as well. Further, no rise in antibodies was observed in the convalescent serums of the four patients with bacterial infection when tested either by the method of complement fixation or by the mouse protection test (table 1 and cases 52 and 53 in table 3).

The general agreement in the trend of the tests of the same serums by the two different methods is of extreme interest. The uniform rise in antibodies in the serum of the patients convalescent from epidemic influenza together with the recovery of virus from such a high proportion of the same patients serves to establish the validity of the results obtained by the different procedures, since they are mutually corroborative.

Furthermore, the negative results in the four cases of straightforward bacterial infection occurring in the same group of persons during the epidemic of influenza suggest that failure to recover virus together with negative serologic tests can properly be interpreted to mean that the case in question is not infection with human influenza virus. In fact, these observations indicate that such cases, although contemporary with the influenza epidemic, were of entirely different origin. The possible value of such observations as an aid to differential diagnosis is apparent.

One person suffering from the disease had as her only complaint coryza with a profuse discharge and without constitutional symptoms other than fatigue, although a mild elevation of temperature occurred on the second day. On the other hand, other persons were observed who, at the time of the influenza epidemic, experienced symptoms characteristic of the common cold without fever but with a subsequent, persistent cough. It was demonstrated by serologic tests that these patients had not suffered from infection with human influenza virus, since the antibody titer of their serum remained unchanged as a result of the experience (table 3, A M and H F).

In table 3 (cases 68 and 69) are also presented data on two subjects who were admitted to hospital as having atypical pneumonia with antecedent illness of four or five days. One of them acquired no definite signs of pulmonary consolidation, the other showed minimal evidence of pulmonary involvement by x-ray and physical examination. Neither had gone to bed before the sudden rise in temperature which occasioned hospitalization. From the sputum of both patients pure cultures of pneumococcus of undetermined type were obtained. Leukocytosis occurred in both instances.

Virus was not recovered from the sputum, but the serologic tests, as evidenced by the high titer of antibodies to the virus in their acute serums, indicated that these two patients were in the stage of convalescence from infection with influenza virus infection at the time of their admission to the hospital.

It seems evident, therefore, that while the great majority of patients exhibit a fairly uniform clinical picture, a small percentage show variations ranging from the asymptomatic to those resembling lobar pneumonia.

SUMMARY AND CONCLUSIONS

While the number of patients included in the present report is small, they appear representative of the epidemic of influenza which occurred in New York City during the past winter. Furthermore, the results of the studies carried out among these patients were striking in their uniformity. The virus recovered during this epidemic either by the inoculation of ferrets or by direct transmission to mice was the same as that which has been isolated in recent years during epidemics of influenza in different parts of the world. The high percentage of clinical cases of influenza in this group in which the virus was actually demonstrated emphasizes the close relationship between the disease and the presence of virus.

Moreover, the demonstration of virus in the nasopharynx of a patient was regularly associated with a subsequent rise of antibodies in the patient's convalescent serum, as measured by the mouse protection test or the complement fixation test. The agreement between the recovery of virus and the development of antibodies serves to indicate that the antibody response is a direct response to infection with influenza virus and can be considered as positive evidence of the disease even though virus is not recovered from the patient's throat.

This is further suggested by the negative results with all procedures in the four cases of incidental bacterial infection observed at the same time. It appears, therefore, that the demonstration of human influenza virus and the development of antibodies to the virus either jointly or alone may be sufficient to warrant a diagnosis of epidemic influenza.

The application of these results to the study of epidemic respiratory disease should be of great value. It permits the more accurate charting of the clinical boundaries of epidemic influenza and by closer association of laboratory procedures with careful clinical observation may serve as a guide in the study of other diseases of similar clinical characteristics.

ABSTRACT OF DISCUSSION

DR FRANCIS G. BLAKE, New Haven, Conn. In addition to further confirmation of the relationship of a characteristic virus to epidemic influenza and the demonstration that the virus isolated in 1936-1937 is immunologically homologous with strains of virus that have been isolated since 1933 from all over the world, this paper includes three other important points. The first is the demonstration that the virus can be quite easily isolated from approximately 80 per cent of cases, without difficulty. The second is the confirmation of the earlier studies of Dr. Francis concerning the increase in antibody titer during convalescence, beginning about a week after onset. The third and perhaps most important point is the utilization of these two laboratory procedures in an effort to define more sharply the variation in the clinical picture of influenza. If these laboratory methods are to be used for this purpose, they must be examined quite critically as to their validity and their accuracy. Since Dr. Francis and his co-workers have failed to isolate the virus in about 20 per cent of the cases, failure

cannot subsequently be taken as a certain indication that a given patient did not have influenza. Obviously, then, the final determination in cases in which one has failed to isolate the virus must rest solely on whether or not there is a higher antibody titer in the serum collected during convalescence than in that collected during the acute stage of the disease. I should like to ask Dr. Francis what he considers a diagnostically significant rise in antibody titer. If the original titer, as occurred in a few cases, was 100, would a convalescent titer of 200 be considered diagnostically significant? Furthermore, it would seem surprising, as I gathered that the authors implied, if every case of influenza should show a rise in antibody titer during convalescence. At least I think it is fair to say that physicians have had no such experience with antibody tests in other diseases. There are always a few that fail to show the usual antibody response. I should like to ask whether there was any relationship between the titer of antibodies early in the disease and the clinical picture. Did patients with high titers have a mild infection, those with low titers a more typical disease?

DR THOMAS FRANCIS JR., New York. The point Dr. Blake raises is the possible relationship between the titer of antibodies in the patient's blood at the time of acute illness and the clinical characteristics of the disease. So far as we have been able to determine, it has not been possible to relate accurately the titer of antibody and the type or severity of illness that ensued. For instance, in the two subjects that were presented, which represented what one might call subclinical infection, the antibody titers of their original serums were certainly no higher than in numerous other individuals who had the typical disease. In the same manner, of the patients whom we did observe who had high titers, there were three in an entire group larger than the present one who had titers of 100, 120 and 200 in the acute illness, and it was not possible to see any very clear difference between their illness and the illness of others who had lower titers. Consequently it leaves the subject open as to the actual mechanism of immunity. I don't think we want to imply that we consider the development of antibodies the sole mechanism of immunity. It can, however, be used as a demonstration of infection. Dr. Blake has raised a question as to what is responsible for the failures in recovering virus. There are perhaps two different reasons that are quite obvious in our experience. The first of these was that with the facilities at hand it was not possible to test all the washings immediately at the time they were taken, consequently, some of these had to be stored until they could be conveniently inoculated into ferrets. Some of the failures might have been due to that. On the other hand, the possibility that individuals had what might be termed an accelerated immune reaction does occur. We have observed in certain animals that, while they may not be entirely immune, inoculation of virus in late convalescence will result in fever but no other evidence of infection. If one tries to recover virus from those ferrets, one usually fails. It is possible that some mechanism such as this does occur in human population as well. As to what rise of antibodies is significant in making the diagnosis, I think it requires really a correlation of all the studies to decide. When one considers the incidence of virus recovery and the results of serologic tests in the same subjects, I don't believe the difference of one dilution can be taken to be extremely significant unless one recovers virus from the patient. On the other hand, when the serums are tested at the same time, a difference logarithmically of twofold is decidedly significant, that is, although the subject may not have antibodies and his titer may go only to 1:15, that has much more significance than a rise from 1:40 in the acute to 1:80 in the convalescent.

Osler's Bibliography—730 Titles.—His charm as a writer had much to do with his great success as a teacher, and his bibliography, covering a period of forty-nine years, is most extensive, 730 titles, including his collected essays and addresses, having been assembled by Miss Blogg in commemoration of his last birthday. There is a great range of subjects besides those pertaining to medicine and medical history.—Cushing, Harvey. *Consecratio Medici and Other Papers*, Boston, Little, Brown & Co., 1928.

STUDIES ON OXYURIASIS

V THERAPY WITH SINGLE DOSES OF TETRACHLORETHYLENE

WILLARD H WRIGHT, PH D

JOHN BOZICEVICH, MA

AND

LEON S GORDON, MD, PH D

WASHINGTON, D C

Oxyuriasis is the subject of a group study in the Division of Zoology, and in connection with this study attention is being given to the matter of developing an effective therapy. Wright and Cram¹ have reviewed many of the methods recommended in the literature for the control and treatment of oxyuriasis, have pointed out defects and inadequacies in some of these methods and objections to the use of others, and have outlined the requirements for a satisfactory therapy. The present paper deals with the results of the treatment of fifty cases of oxyuriasis with single doses of tetrachlorethylene, and supplements a preliminary report² on the use of this drug.

During the late summer of 1936, one of us³ conducted a pinworm survey in a group of more than 200 boys attending the summer camp of the Metropolitan Police Boys' Club near Scotland, Md. Among the group of pinworm cases disclosed by this survey, fifty boys were selected for hospitalization and treatment. For the most part, these individuals were underprivileged boys whose parents were in a low economic-social status and not financially able to employ private physicians. Dr. Edgar A. Bocock, superintendent of the Gallinger Municipal Hospital, provided the necessary hospital facilities and cooperated in carrying out these tests. Mr. J. M. Schaffer, a director of the Metropolitan Police Boys' Club, assisted in arranging the many details of this experiment.

METHOD OF CONDUCTING TESTS

The patients came to the hospital at 4 p. m. on the day of admission and were given a light supper of fat-free foods. At 8 o'clock each was given a high soap-suds enema with the patient in the knee-chest position. At 7 a. m. the next day a second soap-suds enema was given in order to clear the lower bowel and to facilitate the rapid evacuation of the anthelmintic, with the idea of preventing, to some extent, unfavorable reactions to the treatment. No breakfast was allowed. The anthelmintic was administered at 8 o'clock and no food was given until after the bowels had moved copiously, following which the diet consisted of the regular hospital fare. The tetrachlorethylene was administered at a dose rate of 0.1 cc. for each year of apparent (not chronological) age, the drug being given in 30 cc. of a saturated solution of magnesium sulfate plus 60 cc. of water, or in a suitable dose of a solution of magnesium citrate. In order to determine the value of magnesium citrate alone for the removal of pinworms, three of the patients were given a dose of this purgative

without tetrachlorethylene, followed the next morning by a high enema consisting of 1 cc. of tetrachlorethylene in a coconut oil soap emulsion in 1 liter of water. All stools passed following treatment, including those from the enemas, were collected and washed through a series of screens of mesh sizes graduated from coarse to fine, and all worms, including pinworm larvae, were recovered and counted. The patients were discharged at 4 p. m. on the second day after admission.

In addition to the worm count on each individual the results of treatment were checked in a number of ways. To determine whether the patient had been freed of all worms by the treatment, we used the anal swab described by Hall⁴ and designated the NIH swab, a device which has been found eminently satisfactory for the diagnosis of pinworm infestation. Swabs were taken on each individual on approximately the fourteenth and twenty-first days after treatment.

Clinical improvement following treatment was determined by weight records taken before and after treatment and by information obtained by direct interview of the parents of all patients both before and after treatment. In addition to these methods of judging effects of treatment, we obtained from the school teachers of twenty-four of the patients at the end of the school semester, from six weeks to two months after treatment, detailed information relative to any noticeable change in the deportment, general attitude and scholastic standing of the individual. We were assisted in collecting these data and in the hospital nursing of the patients by Miss Edith Adams, R.N., of the staff of the Metropolitan Police Boys' Club. The information from these data will form the subject of a later paper.

Wright and Cram¹ have noted the necessity for adequate post-treatment checks in attempts to evaluate the exact efficacy of any method of treatment for oxyuriasis and have pointed out that apparently most of

the treatments for oxyuriasis, as recommended in the medical literature, are based on clinical evidence only and are not substantiated by the evidence necessary to indicate complete freedom from infestation following the use of the treatment or treatments advocated. In our series of cases, it is realized that two negative swab examinations are not conclusive evidence of complete freedom from infestation, for the reason that in some cases more swab examinations are needed in order to establish this point definitely. However, we found the post-treatment checkup of our series of cases a formidable task, since many of the parents failed to cooperate in seeing that the boys reported for post-treatment examination, and it was not possible to make more than two swab examinations following treatment. In order to arrive at a correction figure for our post-treatment check, Dr Selwyn D Collins, principal statistician of the U S Public Health Service, has analyzed data on 628 individuals examined by swabs for pinworm infestation. The data have been placed at our disposal through the courtesy of Dr E B Cram. Dr Collins's analysis of the data indicates that 70 per cent of cases of pinworm infestation in the Washington groups studied were detected on the first two swab examinations. Our post-treatment check in the present series is therefore probably 70 per cent accurate, and we are accordingly allowing a correction figure of 30 per cent in determining the results of treatment in this series. Because of the high variables in such studies, the appropriate corrective figure would have to be obtained anew for any series of cases studied under different conditions.

REACTIONS TO TREATMENT

Disagreeable reactions to the tetrachlorethylene-magnesium sulfate mixture led us to discard the magnesium sulfate solution as a purgative, and in the later phases of the tests we adopted the use of the magnesium citrate solution. The following symptoms were noted in the twenty-five boys receiving the tetrachlorethylene-magnesium sulfate mixture: dizziness in seven cases, nausea in three cases, vomiting in three cases, headache in two cases, and respiratory depression, cyanosis and loss of consciousness in one case. Of the twenty-two patients receiving the tetrachlorethylene-magnesium citrate mixture, two complained of slight dizziness and two vomited, one of these vomiting before treatment also. It has been the frequent observation of public health workers in administering mass treatments of carbon tetrachloride or tetrachlorethylene in hookworm control campaigns that many individuals complain of nausea, vomiting, dizziness, abdominal pain and other symptoms following the use of these chlorinated hydrocarbons with magnesium sulfate. In investigating the nature of these reactions, Malloy⁵ administered magnesium sulfate solution alone to a number of patients assembled for hookworm treatment and noted that the patients who received the purgative solution alone showed reactions as severe in nature as those exhibited by patients who received carbon tetrachloride with the magnesium sulfate. Malloy believed that some reactions of the before-mentioned character, following the administration of such hookworm treatments, are due to the magnesium sulfate and not to the anthelmintic, an opinion shared by most workers in this field. Hall⁶ has noted that headache, nausea and dizziness occur

in a large minority of cases treated with almost any anthelmintic and usually disappear after the bowels move, an observation which suggests the purgative as the cause.

One of our patients, an 11 year old boy who received 11 cc of tetrachlorethylene in 30 cc of a saturated magnesium sulfate solution plus 60 cc of water, showed symptoms of dizziness and depression one hour after treatment, the extremities were cold and the respirations were shallow. The patient complained of eructations of the drug. One and one-half hours after treatment he became cyanotic and during the next half hour lost consciousness four times. He was given 0.2 cc of a 1:1,000 solution of epinephrine hydrochloride intramuscularly, following which his condition showed immediate improvement. Eight hours after treatment he complained of nausea and vomited several times, he was then given bismuth subcarbonate and elixir of

phenobarbital equivalent to one-eighth grain (0.008 Gm) of the drug. Following this medication he returned to normal. This patient was found later to be suffering from pulmonary tuberculosis, a condition not disclosed by his previous medical history, and three months after treatment was admitted to a tuberculosis sanatorium. Had this condition been known to us, he would not have been treated.

RESULTS OF TREATMENT

For purposes of comparison, the results of treatment have been set down in three tables. Table 1 comprises those patients who received tetrachlorethylene in magnesium sulfate solution, table 2 comprises those patients who received tetrachlorethylene in magnesium citrate solution and table 3 comprises those patients who received magnesium citrate without tetrachlorethylene by mouth but followed by a tetrachlorethylene enema.

Patient 24 (table 1) was treated at camp for the reason that he was a food handler. As facilities were

⁵ Malloy, D. M. Work of the Department of Uncinariasis of Nicaragua in 1924 and 1925. Bull. Internat. Health Board 7: 77, 1926.
⁶ Hall, M. C. Principles and Theories of Anthelmintic Medication. Puerto Rico J. Public Health & Trop. Med. 9: 418 (June) 1934.

not available for screening the stools, the worms passed by him were not recovered. However, this boy was negative on post-treatment swab examinations and is being included in this series. Of the twenty-five cases in table 1, nine were positive and sixteen were negative on post-treatment swab examinations.

In table 2 patients 31 and 32 moved away to a distant state within a week after treatment, so no post-treatment swab examinations were made. Patient 40 passed no worms following treatment and was negative on post-treatment swab examinations. It seems probable that this boy was lightly infested at the time of diagnosis and subsequently lost his infestation spontaneously between the date of his appearance at camp and the time of treatment, an interval of approximately four months. Of the nineteen infected boys represented in table 2 on whom post-treatment checks were made, five were positive and fourteen negative after treatment.

Post-treatment swab examinations in the three cases represented in table 3 indicated that all three boys were negative after treatment. However, it will be noted that in no case did the magnesium citrate solution, preceded by a soap-suds enema, remove all worms, since additional worms were removed by the tetrachlorethylene enema administered on the following morning.

TABLE 3—Results of Treatment for Oxyuriasis with Magnesium Citrate Solution Followed the Next Day by an Enema Consisting of 1 Cc of Tetrachlorethylene and 20 Cc of Coconut Oil Soap in 1 Liter of Water

Case No.	Age of Patient Years	Dose of Magnesium Citrate Solution Cc	Worms Passed Following Treatment				Results of Post Treatment Swab Examinations
			Soap-suds Enema	Stools	Tetrachlorethylene Enema	Total	
48	14	275	9	14	1	24	Negative
49	15	300	41	39	17	97	Negative
50	10	175	5	5	2	12	Negative
Averages	13	250	18	19	7	44	Three cases all negative

Of the forty-seven cases of infestation carried to completion in this series, fourteen were still positive for pinworms on post-treatment swab examinations and thirty-three were negative. Three of these boys did not receive tetrachlorethylene orally, leaving forty-four treated orally. Of these forty-four, fourteen were positive after treatment and thirty were negative. If our correction figure of 30 per cent, representing the percentage of positive cases not disclosed by two swab examinations, is applied to these results, it is found that nine of the thirty cases would probably have been disclosed as positive had we been able to make additional swab examinations. The corrected figures for the forty-four cases would therefore be probably twenty-one negatives, or 47.7 per cent apparently and probably cured. While this is not a high figure, it still appears, as indicated in the paper by Wright, Bozicevich and Rose,² that this is the best single-dose treatment for which we have adequate evidence.

COMMENT

In an analysis of our data we have attempted to correlate the efficacy of the treatment with the degree of infestation. It seems reasonable to assume that heavy pinworm infestations would be more refractory to treatment with single doses of anthelmintics than would light infestations, since in heavy infestations it is more likely that some worms would be located in

the appendix, where they would be reached only through the accidental penetration of the anthelmintic into that organ.

The mean number of worms recovered from individuals receiving tetrachlorethylene in magnesium sulfate solution (table 1) was 139.3 worms. Disregarding case 24, in which no worms were collected after treatment, fourteen of the fifteen remaining cases negative after treatment showed infestations below the mean for the group.

The mean infestation, as indicated by worms recovered, in the group receiving tetrachlorethylene and magnesium citrate solution (table 2), was 431.5 worms. In this group all the cases negative after treatment showed infestations lower than the mean.

In the group receiving magnesium citrate followed by a tetrachlorethylene enema (table 3), all three patients were negative after treatment, in each case the number of worms recovered was relatively small.

The average number of worms recovered from the forty-nine boys from whom stools were secured was 255.8. Only two of our thirty negative cases showed infestations above this mean. This figure and those already set forth indicate, apparently, that tetrachlorethylene is more dependably efficient in effecting cures in persons lightly infested with pinworms than it is in persons heavily infested with pinworms although in cases of heavy infestation the drug will remove many worms. The failure of the drug to effect cures in these heavy infestations, as pointed out previously, may be correlated with the greater likelihood of the presence of pinworms in the appendix, an organ into which the anthelmintic would probably not penetrate regularly but would enter only accidentally, and perhaps correlated also with the probability of an increased dilution factor for the anthelmintic by the time it reaches the large intestine, a factor which might account for its failure to remove all of relatively large numbers of worms although it might remove all of relatively small numbers of worms. While we cannot predict with any degree of certainty that all anthelmintics, or most anthelmintics, when given orally in single doses, will effect cures in many cases of light pinworm infestation and fail to effect cures in many cases of heavy pinworm infestation, it would seem that this result, observed in the case of tetrachlorethylene, might follow even more certainly with those anthelmintics of recognized merit which have a greater water solubility than has tetrachlorethylene. This assumption would seem to apply at least in the case of hexylresorcinol, particularly in view of Brown's⁷ failure and our own clinical failures to clear up pinworm infestations by the oral administration of single doses of this drug.

SUMMARY AND CONCLUSIONS

In experiments reported in this paper, forty-seven boys infested with pinworms were treated with single doses of tetrachlorethylene administered orally at the rate of 0.1 cc for each year of apparent age. The administration of this drug in a solution of magnesium sulfate provoked disagreeable reactions in a considerable percentage of twenty-five cases, but these reactions were largely obviated by the substitution of magnesium citrate as a purgative in the remaining cases.

Of forty-four infested boys who received tetrachlorethylene orally and were checked by post-treatment swab examinations on approximately the fourteenth and

⁷ Brown, H. W. Treatment of Pinworm (*Enterobius Vermicularis*) Infestation with Hexylresorcinol. *Proc. Soc. Exper. Biol. & Med.* 30: 221 (Nov.) 1932.

twenty-first days after treatment, thirty, or 682 per cent, were negative, but the true percentage of cures is probably about 477 per cent as arrived at after the application of a correction figure of 30 per cent for positive cases not disclosed by two swab examinations.

Three boys received magnesium citrate solution alone, followed the next morning by an enema consisting of 1 cc of tetrachlorethylene in a coconut oil soap emulsion to 1 liter of water. These three boys were negative on post-treatment swab examinations, but in no case did the magnesium citrate solution remove all worms.

The number of worms recovered from individuals in these tests varied between 1 and 4,958, the average infestation was 255.8 worms.

Evidence indicated that tetrachlorethylene administered orally in single doses was more effective in eradicating relatively light pinworm infestations than it was in eradicating relatively heavy infestations, since only two of our thirty negative cases treated in this manner showed infestations above the mean.

So far as there is available evidence, it would appear that tetrachlorethylene is one of the best drugs for a single-dose treatment for pinworms. It is especially effective, apparently, for light pinworm infestations but will probably fail to effect cures in the majority of persons heavily infested with pinworms, a failure which would probably be shared by other anthelmintics of merit when similarly administered.

Clinical Notes, Suggestions and New Instruments

MYIASIS

W J BRYAN JR, M.D. TULSA, OKLA.

The term myiasis means the invasion of the tissues or organs of animals, including man, by the larvae of flies. There are a number of species of flies that will invade living animals, even to the most specialized and parasitical types.

These types are, first, Oestridae (bots, warbles). The bots or warbles have under certain cases become highly specialized. The ox warbles (*Hyperma lineata*) confines itself to one host, the relationship being so close that if it should be removed prior to normal maturity it will die. Most authorities believe that the entrance is through the esophagus to the back. The sheep bots (*Estrisovis*) attack primarily animals, as do also the horse bots, but cases are on record in which man has been infected. The eggs are deposited in the mouth or nasal passages, the larvae transferring their location to the sinuses, the base of the tongue or the orbit of the eye. Among Oestridae is also found the species *Dermatobia hominis*, which is the common cause of dermal myiasis in man.

At this time I am writing of the species of flies the larvae of which will attack healthy tissues as well as diseased or traumatized tissues. These species come under the classification of Muscidae and Sarcophagidae. In the United States the Muscidae most commonly noted are *Lucilia*, *Phormia* and *Culliphora*, most commonly known as green bottle, blue bottle or blow flies. These flies deposit eggs on a large variety of human foods most commonly though on cold meats.

Flies belonging to the Sarcophaga group are the ones I am most concerned with in the case to be reported. The Sarcophaga family is especially partial to meat and is also larviparous, that is it deposits living larvae. Under favorable conditions the life cycle is very fast. The maggots develop to full growth in from four to five days after which they leave the host for drier conditions for pupation. The entire cycle from egg to mature fly is from fifteen to eighteen days. This period varies according to conditions.

REPORT OF A CASE

G M., a boy, aged 13 years, came under my observation Aug 9, 1935. His chief complaint was that, beginning at Christmas 1933, diarrhea developed, resulting in from four to six liquid stools each day, with no abdominal cramps or vomiting. The stools at first contained undigested foods but no blood. There was no elevation of temperature and no loss of weight. This frequency continued for from two to three months, with a gradual increase in the odor of the stools and tenesmus. There was a marked halitosis. He was put on a low carbohydrate diet, which seemed to reduce the diarrhea. For the next three or four months he would have from one to four stools a day, then from seven to ten days there would be a week or ten days of diarrhea, in which from nine to twelve very foul stools were passed. In August 1934, acute tonsillitis developed. The maximum temperature for three days was 103 F. Following this the diarrhea became severe there being almost constant stools. The mother stated that there must have been from thirty to forty stools a day. After one week's duration the stools became bloody and mucopurulent, with a terrific odor. Abdominal cramps and anorexia were present. This attack lasted for three weeks, gradually the stools were reduced in number to from four to six each day.

During December 1934 he had only one stool each day and was eating everything. In January 1935 he had diarrhea again, passing from four to eight stools each day. Then from January to June he had daily, four or five stools. In June there was another flare up, in which about twenty stools a day were passed. The stools were bloody and mucopurulent. There was never any nausea or vomiting. Since this period he has had from five to ten stools each day, all being bloody. One month ago a severe attack of nausea, vomiting and diarrhea occurred. There is nothing of any importance in his past history, except that as a baby he had had some intestinal disorders of short duration. The patient was susceptible to colds. There had been some tonsillitis. The tonsils had been removed. There had been no headaches or dizziness and no chronic nasal discharge and no chronic cough or any symptoms referable to the lungs, heart or genito-urinary tract. At times recently some swelling of the hands, knee and ankle joints developed, with a few red blotches over the skin. This never lasted more than from one to three days.

On examination the patient was slender, sallow appearing and underweight, with markedly dry skin and hair. The mucous membranes were of fair color. The temperature was 99.4 F, the pulse 108. He weighed 82 pounds (37 Kg) and was 61½ inches (156 cm) tall. The examination was negative, except that the lower part of the abdomen was distended. There was much gas. The liver, spleen and kidneys were not felt. The sigmoid rolled under the fingers and was very tender, there was also tenderness throughout the abdomen but no rigidity. The patient was referred to Dr C A Pay for examination of the head and a negative report was obtained. X-ray study of the gastro intestinal tract revealed nothing except a small defect on the anterosuperior wall of the first part of the duodenum and evidence of a marked spastic colitis. The colon was ropelike from the cecum to the rectal pouch. Roentgenograms of the chest showed only slight peribronchial thickening. There was no evidence of a tuberculous lesion.

The gastric analysis at forty-five minutes, 50 cc of 7 per cent alcohol solution having been used for the test, revealed free hydrochloric acid 17 per cent, total acid 27 per cent, combined acids 4 per cent. Microscopically mucus and some pus cells with a few red blood cells were seen. Culture from the blood agar plate was negative. The urine was normal. The blood Wassermann reaction was negative. The hemoglobin was 87 per cent (14.5 Gm per hundred cubic centimeters), red blood cells 4,570,000, white blood cells 8,300, polymorphonuclear neutrophils (lobulated) 27 per cent, polymorphonuclear bands 33 per cent, polymorphonuclear eosinophils 17 per cent, small lymphocytes 14 per cent, large lymphocytes 1 per cent, large mononuclears and transitionals 8 per cent.

Specimens of the stools were obtained in the laboratory and were collected in a clean glass beaker. Microscopically they consisted of pus, mucus and blood. No ova or amebas were found. Cultures made on blood agar plates at 37.5 C showed a heavy growth of hemolytic and nonhemolytic *Bacillus coli*.

after twenty-four hours. After another twenty-four hours at room temperature a large number of maggot-like organisms were found on the plates. August 12, this procedure was repeated with identical results, that is, after forty-eight hours numerous maggots were obtained on the plates. We felt that there was no possibility of contamination because the stools were collected in the laboratory, there were no flies present, the beaker was freshly scrubbed before being used and the stool was covered immediately. August 14 a third examination and culture was made, this time a sterile beaker being used. No growth was obtained on the blood agar plates, but the stool, which was also incubated at 37.5 C for twenty-four hours, was teeming with maggots. This stool was covered immediately after passage, sealed and placed in the incubator and never opened.

The sigmoidoscope was then introduced for 16 cm. It revealed the entire mucous membrane to be markedly injected and granular. Numerous ulcers varied from the size of a pin-head to 1.5 cm. These ulcers were crater-like and the floor was covered with a grayish bloody purulent membrane. This membrane wiped off easily, leaving a red bleeding surface. No scar tissue was present and no living organisms were observed. Cultures were made with sterile cotton swabs, the swabs being immediately placed in 7 cc of 0.85 per cent sterile saline solution, one 5 mm loop of this material was streaked on the blood agar plates. On one plate a small portion of mucus from the swab was used. Within forty-eight hours on three of the four plates there developed a flourishing crop of maggots. Specimens of these maggots, both on plates and in the stool itself, were forwarded to Maurice C. Hall, chief of the zoological division in the U. S. Department of Agriculture. Mr. C. T. Greene of the U. S. National Museum identified the larvae as *Sarcophaga haemouidoides* Fallen (gray flesh fly). The Oklahoma Agricultural and Mechanical College also received specimens, and their identification was the same.

Incubations of stool specimens were repeated frequently with positive results. August 20 no growth either in the stool or on the plates was obtained. August 22 another stool was examined and incubated. No maggots were obtained in the stool, but on the plates the larvae appeared in forty-eight hours. August 26 we obtained negative results. The larvae of a previous culture were kept for four days in the stool medium and then several full grown specimens were planted in dry sandy soil that had been sterilized in the dry sterilizer. These required nine days to pupate to the fly. Each time the gray flesh fly was obtained. During the interval the patient continued to have from four to nine stools a day. The blood count remained about the same as previously mentioned, with the eosinophils varying from 14 to 17 per cent. During this investigation a rectal fistula developed. The patient was sent to the hospital and colonic irrigations of thymol were given. The fistula was operated on by Dr. Fred Y. Cronk. His progress in the hospital was fairly satisfactory with four courses of thymol irrigations. On discharge from the hospital we were unable to culture any larvae from the stools, and since that time neither in the stools nor from the smears taken directly from the colon mucous membrane. On examination the ulceration appears much improved but not well by any means.

COMMENT

Knowledge of intestinal myiasis to date and the type of fly involved in this case would point to the fact that it is acquired originally through ingesting cold meats. *Sarcophaga* being carnivorous. This patient, however, lived in a clean, modern home, and his mother used all care possible in the preparation and storing of food. The other alternative in the long duration of the illness, with periodic severe attacks of diarrhea, is that of pedogenesis, that is the ability of grown larvae to produce other larvae in the intestinal tract. Numerous attempts were made to procure eggs from small and large larvae, but with negative results. Identification of ova was attempted from stools but this was impossible. To date I have been unable to produce an artificial medium that would simulate the intestinal tract. If one were able to do so it might be possible to further our knowledge in the habits and life cycle of this species of fly.

ENDOMETRIAL CYST OF THE UTEROSACRAL
LIGAMENT

S. LEON ISRAEL, M.D. PHILADELPHIA

This case report, in which a solitary endometrial cyst of one uterosacral ligament is described, is of interest because such a lesion is rare.

REPORT OF CASE

Mrs. R. C., a white woman, aged 40, admitted to the Mount Sinai Hospital, April 16, 1935, complained chiefly of a constant, dull pain in the left lower part of the abdomen of two months' duration. There were no associated gastro-intestinal or urinary symptoms. The menarche had occurred at 14 years, the menses appearing thereafter every twenty-eight to thirty days for three days. She said there had been no dysmenorrhea but stated that her last menstrual period, March 20, had been accompanied by an augmentation of the already present, left-sided abdominal pain. Aside from a single normal pregnancy twenty years earlier, her past medical history was irrelevant. She had never had either a vaginal or an abdominal operation.

On admission, the patient's temperature, pulse and respiratory rates were normal. The blood pressure was 124 systolic, 74 diastolic. General examination was negative, with the exception of several carious teeth, slight vertebral lordosis and moderate obesity. A soft, round, slightly mobile and tender tumor, which seemingly arose from the pelvis in the midline, filled the lower part of the abdomen. Bimanual (pelvic) examination revealed that this mass filled the posterior cul-de-sac. The vaginal mucosa moved freely over its surface, and the normally sized uterus lay anterior to it. Urinalysis, blood count, blood urea nitrogen and blood sugar were entirely normal. The serologic reactions were negative. A barium sulfate enema roentgenogram delineated a completely normal colon.

The preliminary diagnosis was ovarian cystadenoma.

An exploratory laparotomy was performed April 22, and a hemorrhagic cyst the size of a grapefruit was found attached by a broad base to the left uterosacral ligament. The uterus and its adnexa appeared normal. Excision of the cyst, subtotal hysterectomy, bilateral salpingo-oophorectomy and appendectomy were performed. The abdominal wound healed by primary intention and the patient had an uneventful convalescence. She was discharged from the hospital in good condition on the thirteenth postoperative day.

The patient was seen several times during the course of the following eighteen months. When last examined, Dec. 11, 1936 she was symptom free and presented a healthy, well supported cervical stump.

Pathologic Report (Dr. David R. Meranze).—The excised cyst contained 16 ounces (480 cc.) of thick (syrup-like) dark brown fluid and, in the collapsed state, measured 8.5 cm. in diameter. Grossly the cyst wall presented nothing of especial interest. Microscopic study, however, revealed the presence of fibrous and muscle tissues. It was lined with a single layer of flat epithelial cells, except for one surface. The latter was lined with a gland-containing tissue, which in all respects resembled endometrium as shown in the illustrations. The cyst was considered to be an endometrioma which developed in a ligamentous structure.

The appendix and fallopian tubes showed nothing of exceptional pathologic interest. One ovary had several follicle cysts and the other contained a mature, well developed corpus luteum. The uterus was normal, and its endometrium was of premenstrual (secretory phase) type. In this respect it is interesting to note the strong resemblance that the glands of the endometrioma bore to those of the endometrium itself. As may be seen in figure 2, the epithelial proliferation (giving a saw-tooth appearance), the basal location of nuclei and the frayed character of the lumen surface indicate a response to the corpus luteum principle.

COMMENT

The fact that uterosacral endometriomas are uncommon was stressed many years ago by Cullen¹ who stated with reference to them: "I know of only one case of this character." My colleague Dr. W. W. Russell, removed a pea-sized nodule

from the uterosacral ligament.¹ Ten years later Smith² in reporting 159 endometriomas described two that occurred at the base of the broad ligament. More recently Dawson³

Fig 1—Section (X 100) of portion of cyst wall showing stroma and glands resembling endometrium

Fig 2—Section (X 430) of gland in central portion of figure 1. Note the saw tooth appearance (epithelial overgrowth), basal nuclei and frayed interior surface of the gland and the swollen stromal cells suggesting premenstrual (secretory phase) endometrium

reported a similar case. Keene and Kimbrough⁴ do not specifically refer to such lesions in their description of intraperitoneal endometriosis.

⁴ Keene F E, and Kimbrough R A Jr. Endometriosis in Curtis A H. *Obstetrics and Gynecology*. Philadelphia W B Saunders Company 1933 vol 3.

The etiology of endometriomas in this location in association with generalized pelvic endometriosis⁵ may be readily understood. However, more interesting is speculation concerning the pathogenesis of such a solitary endometrioma so far removed from both the endometrium and the tubal ostia in a woman having no surgical history. It seems unlikely, more especially in the absence of adenomyosis of the uterus that the lesion could have been derived either from direct endometrial extension⁶ or by reflux of menstrual blood and endometrium through the fallopian tubes.⁷ An endocrinopathic origin⁸ of this cyst seems improbable because of the presence of a mature corpus luteum in one ovary and the apparent response of both the endometrium and the aberrant glands to the progestin elaborated by it (fig 2). Sitzenfrey's⁹ theory suggesting a derivation from lymphatic endothelium might be applicable in this instance since the uterosacral ligaments are richly endowed with lymphatic vessels. However the most attractive explanation for such an oddly placed endometrioma is the serosal metaplasia theory proposed long ago by Iwanoff¹⁰ later championed by Meyer¹¹ and more recently approved by Nicholson¹² and Novak.¹³ This hypothesis based on the coelomic origin of müllerian tissue serves to explain many similar lesions because it suggests that heterotopic peritoneal (coelomic) epithelium may give rise to endometriomas by metaplasia.

PRIMARY HYPERPLASIA OF THE THYROID IN ONE OF STILL BORN TWINS

SHIELDS WARREN, M.D. AND LEONARD B. SHPINER, PH.D., M.D.
BOSTON

Many observers have reported the postnatal development of various disease entities in either one or both of fraternal and identical twins. There have been many hypotheses advanced as to the operating causes producing these changes. A perusal of the literature reveals that marked primary hyperplasia of the thyroid in one of still-born twins probably identical has not been reported. Because of the relatively early stage of fetal development a clearer evaluation of the inciting factors involved can be obtained in this instance.

REPORT OF CASE

History—C. S., a woman aged 34 admitted to the Lahey Clinic September 29 complained of a swelling of the neck of two years duration. The patient said that there were no symptoms of toxicity except for a loss of from 30 to 35 pounds (14 to 16 Kg.) over a period of three years. The patient a quadripara at this time was three months pregnant. The third child had been stillborn. A bilateral phlebitis developed following the birth of her last child. Other history was essentially noncontributory.

Examination—The patient was highly activated and apprehensive with warm moist skin and a slight stare. Her weight was 165 pounds (75 Kg.) pulse 120 blood pressure 150 systolic, 70 diastolic. There was a marked pulsation of the vessels of the neck, palpitation and tachycardia were also present. The thyroid gland was three times its normal size.

From the Laboratory of Pathology, New England Deaconess Hospital. Dr K B Lawrence dissected the twins and supplied the sketch shown in figure 1.

The Wassermann reaction was negative red blood cells numbered 3,620,000 with hemoglobin 68 per cent white blood cells 12,800, polymorphonuclear leukocytes 81, lymphocytes 17 and large monocytes 2 per cent. The basal metabolic rate on entrance was +62.

The clinical diagnosis was primary hyperthyroidism. Complete bed rest and iodine medication brought the basal metabolic rate down to +29 four days before the first stage of the operation.

Fig 1—Drawing of larynges with thyroids attached showing size of the thyroids of the twins in relation to the larynx.

Operation—First Stage *October 10, the first stage of the hemithyroidectomy was done on the right. The thyroid presented a somewhat variable appearance but was markedly hyperplastic. There was but little stroma and there were fairly numerous dilated blood vessels. The follicles varied from small clusters of columnar cells devoid of colloid through large branching follicles devoid of colloid to moderate sized, or even large, follicles containing fairly compact colloid. The epithelium was predominantly columnar, although there were foci in which the follicles were lined by cuboidal cells or even by flat epithelium. Rare foci showed follicles lined by flattened epithelium and distended colloid. The diagnosis at this time was primary hyperplasia with irregular involution and foci of hyperinvolution.

Second Stage After six weeks of iodine medication and bed rest she was again admitted to the Lahey Clinic for the second stage of the operation. The basal metabolic rate two

Fig 2—Section through thyroid trachea and esophagus of twin with impaired circulation. Phloxine methylene blue stain reduced from a photomicrograph with a magnification of 10 diameters.

days before operation was +6. The patient now was five months pregnant and had felt life the week prior to her entrance into the hospital. Owing to the fact that vaginal bleeding also developed at this time she was put at complete bed rest. November 23 the second stage of the hemithyroidectomy was done on the left. Microscopic examination revealed that practically the entire section was occupied by moderate sized follicles lined with low cuboidal to flat epithelium and filled with fairly compact colloid. There were rare papillary projections into the follicles and some branching although in general the con-

tour was even. In scattered foci were large follicles distended with colloid and lined with flat epithelium. The diagnosis was primary hyperplasia with late involution and foci of hyperinvolution.

Three days following the second partial thyroidectomy the first fetus was delivered as stillborn of the male sex. Two hours later the patient passed a small amount of placental tissue and another fetus of the male sex was delivered, the placenta was then expelled in toto.

We consider the twins identical because of the following observations: 1. The twins were both males, of the same size and same stage of development, except for the thyroid and for edema of the right arm from a twisted cord in one of the twins. 2. There was one placenta monootyledonous. Points of uncertainty arose from the failure to demonstrate placental attachment of the second cord and from failure to reconstruct the placental fragments first passed.

Pathologic Examination—The specimen consisted of two fetuses, both males, each 27 cm long, each weighing 300 Gm. and one placenta with one cord arising from it. The cord had one turn over the chest and one loop around the upper right arm of one of the fetuses and then passed to the placenta. That there had been considerable compression was evidenced by marked edema of the hand and the arm up to the point of compression. The diameter of the right arm was one third greater than that of the left arm. The placenta measured 11 by 12 by 3 cm. The one cord attached measured 22 cm long. The placental tissue was soft and somewhat fragmented and to it was attached considerable elastic blood clot. On dissection of the fetuses the viscera appeared normal with exception of the thyroids. In the fetus with the edematous arm the thyroid

Fig 3—Section through thyroid trachea and esophagus. Note parathyroid at margin of thyroid tissue. Thyroid from twin with normal circulation. Phloxine methylene blue stain reduced from a photomicrograph with a magnification of 10 diameters.

appeared pale red-brown and of a meaty texture, each lateral lobe measuring 1.3 by 0.7 by 0.4 cm. In the other fetus the thyroid was pale and fibrous, each lateral lobe measuring 0.9 by 0.6 by 0.3 cm (fig 1). The parathyroids were not identified grossly in either fetus.

The pituitary in the fetus with the enlarged thyroid was grossly normal. There was no abnormality evident of the other glands of internal secretion. There was no tracheal compression by the thyroid in either case. The thyroids were not weighed separately but were fixed in toto with the trachea and adjacent tissue (figs 2 and 3) in the hope of finding the parathyroids which proved to be normal microscopically.

Microscopic Examination—Fetus with the Large Thyroid and Twisted Cord. The thyroid tissue was highly vascularized. Fibrous stroma separated individual acini and slightly more definite bands of connective tissue somewhat edematous separated the lobules. No solid masses of thyroid cells were present. A few apparent masses were seen, on serial sections to represent tangential sections of follicles. Lumens of follicles varied markedly in size, from approximately 10 to 100 microns in their greatest diameter. Some of the larger follicles contained heavily scalloped colloid. Traces of granular precipitate apparently representing colloid were present in a few of the smaller follicles. Some of the larger follicles showed branching. Rarely papillary projections into the lumens were suggested. The epithelium ranged from columnar to high cuboidal. There was a slight variation of nuclear size. Mitotic figures were not seen (fig 4).

Second Fetus Tissue of the smaller thyroid was made up largely of well defined follicles. No definite cell masses were made out. Lobulation was rather less distinct than in the first fetus. A majority of follicles contained colloid apparently well defined, with slight or no scalloping. Lumens of follicles ranged from 10 to 80 microns, with the majority about 30

Fig 4—Section of thyroid from twin with impaired circulation showing hyperplasia. Phloxine methylene blue stain, reduced from a photomicrograph with a magnification of 475 diameters.

microns in diameter. The epithelium ranged from cuboidal to low cuboidal. The nuclei were fairly uniform. No mitoses were seen (fig 5).

COMMENT

Clinicians have assumed the following etiologic factors as being causative agents in influencing pathologic changes in one or both of fraternal and identical twins: syphilis, maternal exhaustion, endocrine imbalance, atavism, defect of the germ plasma, and neuropathic familial taint. Neff¹ reported a case of exophthalmic goiter in identical twin girls developing at 8 and 10 years of age respectively, as being due to an apparent dietary deficiency. It seems that no single etiologic factor can stand the test.

Involution of the thyroid gland may occur under the following conditions: (1) spontaneous development, (2) administration of iodine, (3) partial thyroidectomy, (4) change of diet, (5) treatment with x-rays, (6) altered blood supply.

From the salient features of our case we postulate the following *modus operandi*: Antedating conception and continuing to the period of stillbirth of the twins, the mother developed marked symptoms of hyperthyroidism, had been medicated with iodine and underwent two partial thyroidectomies. In utero at first and almost throughout life the twins were subjected to the same environmental influences. The initial pathologic changes might have originated with abnormal thyroid anlagen and the subsequent transmission of the hormones across the placental barrier affected the twins equally so that they mirrored the pathologic condition of the mother, the two developing primary hyperplasia to the same degree. This is in accordance with the observations of Siemens² who stated that in spite of the exogenous causes of endemic goiter it is

conditioned by hereditary influence, since it practically always, if present, affects identical twins to the same degree.

However, in the further fetal development, the mechanical factor of the twisted cord (one turn over the chest and one loop around the upper right arm, to the point of producing compression edema) in one fetus, intervened to cause differences in the reactivity of their thyroid glands. Whereas the thyroid of one fetus underwent involutionary changes parallel to the clinical improvement of the mother to the point of approaching the upper limits of normal, the thyroid gland of the twin with the twisted cord remained static, showing only the primary hyperplasia that the mother had at first shown, and practically no involution was microscopically discernible.

Taking cognizance of the fact that histologic normality of a tissue may not be a criterion of its physiologic activity nevertheless, by the accepted standards of judging pathologic conditions there were no other changes noted in the fetuses. It seemed to us that the differences in the thyroid glands suggested a qualitative rather than a quantitative response to the circulating hormone. It is tenable to assume that one of two or both pathologic changes took place in the thyroid gland of the fetus with the compression edema.

1. Owing to the reduced circulating volume of the blood through the thyroid gland there occurred an alteration in the pH , this inactivated the thyroid struma at a time of maximum hyperplasia and through the progressive development of this alteration in pH the thyroid was unable to assimilate or mobilize an adequate amount of hormone.

2. Owing to the concomitant development of the thyroid hyperplasia with the progressive alteration in the pH of the blood, the thyroid hormone was shut off from its normal intermediary catalyst, the thyroid gland, becoming inactivated or rendered inert.

Fig 5—Section of thyroid from twin with normal circulation showing evidence of hyperplasia and involution. Phloxine methylene blue stain, slightly reduced from a photomicrograph with a magnification of 475 diameters.

CONCLUSION

We wish to avoid generalizations on the basis of our observations in this one case. However, our case demonstrates clearly (1) the factor of organic inheritance of primary hyperplasia of the thyroid in twins, almost certainly identical, and (2) that mechanical factors may alter the character of the blood supply, thus rendering the thyroid gland inert to change.

SYMMETRICAL ADRENAL NEUROBLASTOMA METASTASIZING TO THE RIGHT AURICLE

JOSEPH C. DOANE, M.D. AND LEON SOLIS-COHEN, M.D.
PHILADELPHIA

The antemortem diagnosis of tumors of the heart is quite rare, probably because alterations in the normal size, shape, rhythm or valvular sounds of the heart are usually attributed to some of the more usual degenerative or infectious pathologic states. Even though a primary neoplasm has been detected and the possibility of cardiac metastasis has not been forgotten by the clinician, the actual diagnosis of this condition is often made

Fig. 1—Cardiac enlargement to the right. Right cardiac border flattened and dense in appearance. Metastatic nodule in right lower lobe of lung.

only at the postmortem table. The patient who serves as the subject of this communication presented marked evidences of a disease state the symptoms of which suggested vascular inflammation or obstruction affecting the right lower limb. As will be detailed, a malignant tumor of the heart was diagnosed ante mortem. The location of the primary neoplasm, while erroneously suspected to be the pelvis, was discovered only at autopsy. Moreover,

the service that the x-rays and the electrocardiograph rendered in explaining certain cardiac symptoms and signs was of the greatest aid in pointing to the condition actually revealed. The nature of the primary neoplasm and its bilateral location added interest to the case.

It is not uncommon to find a bilateral adenoma of the adrenal cortex. It is unusual to discover, however, as in this case, a symmetrical bilateral neuroblastoma of the adrenal medulla. While cortical adrenal tumors are most commonly adenomas, they are occasionally carcinomas. Tumors of the adrenal medulla may be pheochromocytomas, ganglioneuromas or neuroblastomas. The latter term was originally employed by Wright¹ in 1910. Bailey and Cushing² applied the term "sympathicoblastoma" to these tumors, although this term implies a more anaplastic neoplasm and an earlier phase in the stage of embryologic development. Grossly these tumors are soft and hemorrhagic and often exhibit areas of necrosis. Metastases are likely to be widespread and follow venous or lymphatic channels. Holmes and Dresser³ have pointed out the frequency of skeletal involvement. The adrenal cortex may be extensively invaded. When this is the case hypotension, pigmentation, asthenia and other well known symptoms of adrenal dysfunction may be observed. In the case to be presented, although but little normal functioning tissue remained such symptoms until very late in the disease were conspicuous by their absence. Both kidneys were secondarily involved, the renal vein was invaded and a number of metastatic nodules could be traced to the superior vena cava with direct extension to the right auricle (fig. 1). Secondary metastasis to the pleura and retrocardiac space was also present. The right auricle was dilated in consequence of the mechanical obstruction to the outflow of venous blood caused by the neoplasm jutting out from the auricular wall.

REPORT OF CASE

History.—J. H., a man, aged 62, a baker, admitted to the Jewish Hospital March 17, 1936, complained of pain in the right leg of five weeks duration, swelling of the right leg of

two weeks' duration, and inability to walk of one week's duration. The patient had been under the care of a physician for five weeks, various therapeutic measures having been instituted without relief. For the past week walking had caused such great distress that he had remained in bed. His past medical history was negative except that he had suffered some loss of weight during the past month. He had experienced night sweats but no hemoptysis.

On admission the patient's skin appeared wax and pale. There was no dyspnea, cyanosis or jaundice. The pupils were regular in outline but the left pupil was dilated and did not react to light. The ocular movements were normal. The tonsils and teeth were grossly infected. Physical examination of the chest was negative. Examination of the abdomen was difficult owing to the patient's inability to assume the dorsal position, but no gross pathologic condition was discovered. The right leg from the toe to the thigh was swollen to thrice its normal size. There was an absence of pulsation in the right dorsalis pedis and posterior tibial arteries.

A provisional diagnosis of phlebitis, embolism of the femoral artery or a pelvic tumor, probably malignant, with obstruction of the venous channels of the right limb was made.

During the patient's stay in the hospital the swelling of the leg subsided considerably. Auricular flutter developed, March 28, with accompanying moderate dyspnea. April 2 the patient became extremely weak, somnolent and dyspneic. A thrombotic process in the midbrain was suspected. Lethargy increased April 4, and the auricular flutter persisted. A neurologic examination, April 9, assigned the third nerve palsy to a vascular cause. April 10 fluoroscopy of the chest revealed an enlarged right side of the heart, diminished pulsation, and fixation of the right border of the cardiac shadow. This led us to suspect an infiltrating process of the right auricle and myocardium. Film study confirmed the enlargement of the heart. A dense shadow adjacent to the right hilus and right border of the heart was interpreted as possible atelectasis (fig. 1). April 13 the spinal fluid was found to be under increased pressure (22 mm. of mercury). The blood pressure on this day was 95 systolic and 60 diastolic. The patient died, April 14, twenty nine days after admission.

Special Studies.—The x-ray examination revealed no evidence of an organic lesion of the colonic tract. March 6 the post-

Fig. 2—Autopsy specimen of heart viewed from epicardium shows malignant mass in right auricle.

ability of a tumor of the heart and atelectasis or neoplasm of the right lower lobe of the lung was suggested by x-ray examination.

The electrocardiogram on March 26 suggested the presence of a recent right branch coronary thrombosis and on March 28 an auricular flutter was diagnosed. April 10 an auricular ventricular heart block was present.

The urine continually contained a trace of albumin with hyaline and granular casts and a few white blood cells. The Wassermann reaction was negative.

At autopsy the right auricle was found to be almost completely infiltrated by a myocardial and endocardial malignant process with grayish white masses protruding into its chamber. The malignant nodules extended up into the lowermost portions of the superior vena cava the orifice of the latter being partially occluded by this tissue. The malignant process stopped abruptly at the tricuspid valve. The right coronary artery

Fig 3—Autopsy specimen of heart viewed from within showing malignant mass

showed pressure from the thickened grayish white mass. There was involvement of the neurogenic mechanism of the heart which accounted for the auricular flutter and the heart block. The left auricle showed secondary malignant nodules breaking through the entire auricular septum. The ventricles were not involved (figs 2 and 3). The right kidney showed a malignant

nodule 2 cm in diameter near its pelvis. The retroperitoneal glands were all markedly enlarged. The lowermost portion of the vena cava and the right common iliac vein were compressed by malignant glands the size of small walnuts, accounting for the swelling of the leg. There were no gross lesions in the brain. Secondary malignant nodules were found in both lungs. The spleen weighed 1 000 Gm. The primary growth was found in the adrenals. Both adrenals were enlarged to the size of a normal kidney (fig 4). Histologically this tumor was found to be a neuroblastoma of the adrenals with metastasis to the heart.

COMMENT

It has been indicated that metastatic tumors of the heart are rarely diagnosed antemortem from clinical symptoms. Moreover that the occurrence of metastasis to the heart is not frequent is indicated by the statistics in the accompanying table derived from a comprehensive review of the literature as reported by W. M. Gayer.

Burke⁴ reported fourteen cases of metastatic tumors of the heart among 327 autopsies performed in cases of known malignant growths. In none of these patients were the valves found to be involved. This writer also pointed out that in no instance was an antemortem diagnosis made, since cardiac symptoms were not demonstrated during life. Moreover in this series the majority of cases presented more involvement of the left than of the right side of the heart and in all x-ray evidence was lacking. In only one of these cases was the original neoplasm an embryonal renal tumor.

Polp⁵ reported in 1932 a case of sarcoma of the appendix with metastasis to the right auricle producing through infiltration of the cardiac muscle, weakened pulsation, which phenomenon was observed as in this case by means of the fluoroscope. The electrocardiographic diagnosis of coronary thrombosis is no doubt explained by partial obstruction of this vessel by malignant tissue. The involvement of the right side of the heart was due to invasion through the renal vein and interior vena cava.

CONCLUSION

An extensive bilateral adrenal cortical neuroblastoma invading the renal parenchyma and vein exhibited the following features:

- 1 Massive metastasis to the right auricle giving rise to an interesting symptom picture
- 2 Absence of secondary sexual changes

Fig 4—Kidney and adrenal showing tumor mass

3 Swelling of the right lower extremity which was the symptom necessitating hospitalization

4 Fixation and decreased pulsation of the right border of the heart which was observed fluoroscopically, pointing toward cardiac metastasis

*Special Clinical Article*CONGENITAL AND PRENATAL
SYPHILIS

CLINICAL LECTURE AT ATLANTIC CITY SESSION

HAROLD N. COLE, M.D.

CLEVELAND

Various terms have been employed to denote syphilis in the new-born. The commonest are "congenital syphilis" and "hereditary syphilis," and yet neither is exactly correct. When one uses the term hereditary syphilis, it immediately brings up the idea of a condition transferred from mother to child according to certain laws of heredity. The word congenital, on the other hand, implies a child "born with syphilis existing at or from birth." In certain cases this might be correct, and again it might not bring out the true significance. If possible, it would be preferable to indicate in the definition the duration of the disease, its exact implication. The term "prenatal syphilis" has been suggested by Kolmer, *i. e.*, syphilis before birth. This has been adopted by the Cooperative Clinical Group. Hoffmann has suggested the term "syphilis innata," *i. e.*, inborn, existing in one from birth, for the severe fetal forms, and "syphilis connatalis," *i. e.*, born with, and "syphilis postnatalis," *i. e.*, after birth, for the milder types which appear after birth but which are diaplacental. Diaplacental, of course, refers to the fact that the infection has taken place through the medium of the placental tissues and differentiates such cases from the rare cases in which the child is infected in passing through the birth canal. In such a child a local primary lesion develops, followed later by a secondary eruption, and the infection is in the true sense acquired syphilis in the infant. For the purpose of this paper the term prenatal syphilis will be employed for syphilis contracted by the placental route. *Spirochaeta pallida* are conducted by way of the blood stream to the maternal side of the placenta and deposited. Foci of syphilitic change then occur in the placental tissue with further extension to the fetal circulation and thus throughout the fetal tissues. Spirochetes are relatively infrequent on the maternal side of the placenta and more numerous in the fetal portion, possibly because the fetus lacks immunity to the infection while the mother has a certain amount of resistance to the syphilitic invasion.

HISTORICAL REVIEW¹

Torella, 1498, Vella, 1508, and Cataneus, 1516, had the idea that a mother's syphilis was transferred to the child in its passage through the birth canal or later from infected milk or infected mammae. Fallopius, body physician of Pope Alexander VI and of Pope Julius II, noted that wetnurses were infected from syphilitic babies and in 1504 gave the first clinical description of the syphilitic fetus. Paracelsus, 1529, seemed to have some idea of the true significance of prenatal syphilis and mentioned that syphilitic parents under some conditions did not pass the disease on to the child. Ferrier, body physician of Catherine de

Medici, thought the infectious virus was contained in either the male or the female seed, or if the mother was first diseased on the day of conception, then the bad juices were carried from the mother to the fetus. In other words, he seemed to grasp much of the problem as to possible maternal and paternal transmission and diaplacental transmission. The writings of both these authors were apparently neglected until the time of Astruc, 1738, who thought the poison might come from the father or mother. Van Swieten and Boerhave had much the same ideas. The great John Hunter, on the other hand, felt that only primary syphilis was contagious and consequently was forced to deny entirely the possibility of prenatal syphilis. Ricord recognized prenatal syphilis and inoculated some

Fig. 1—Early prenatal syphilis: bullous eruption of the hands and feet.

2,500 persons with syphilis in his desire to combat Hunter's theory that syphilis and gonorrhea were the same disease.

Abraham Colles in 1837 made several interesting observations on syphilis. Thus he noted that an apparently healthy man might get married and transfer syphilis to his wife without showing any evidence of the disease himself. He also mentioned a further important item without attempting to explain it: "One fact deserving our attention is this, that a child born of a mother who is without any obvious venereal symptoms and which without being exposed to any infection subsequent to the birth shows this disease when a few weeks old. This child will infect the most healthy nurse whether she suckle it or merely handle it and dress it, and yet the child is never known to infect its own mother even though she suckle it while it has venereal ulcers of the lips and tongue."

Profeta in 1865 proposed a dictum somewhat different from Colles'. In certain apparently healthy children he noted no clinical syphilis even though they

were nursed by then syphilitic mothers. In other words, some children seemed to have an immunity to the disease. The later discovery of the Wassermann reaction showed the true situation—the children were syphilitic but did not always show it clinically.

Somewhat later than Colles, Jonathan Hutchinson came on the scene as a profound student of medicine as well as of syphilology. He noted the relationship between interstitial keratitis and certain peculiar changes in the teeth. These symptoms along with disease of the eighth nerve are known the world over today as Hutchinson's triad. Moreover, some years before Kassowitz he had called attention to the decreasing virulence of a syphilitic infection in a syphilitic mother as concerning successive children. He and the French syphilologist Alfred Fournier did much to decry the practice of vaccination with the "scab" because of many cases in which syphilis was thereby transferred.

FREQUENCY OF PRENATAL SYPHILIS

The incidence of prenatal syphilis varies greatly according to countries, population and race. The social status and education, likewise, have a bearing on the situation. In Russia prenatal syphilis as well as syphilis insontium, are very common. On the other hand, in Denmark the last case card is indexed, and Hoffmann² quoted Lomholt to the effect that in 1931 there were but twenty-nine cases. Hoffmann said that the German census of 1927 revealed 7,500 living children with prenatal syphilis. This figure probably is low. Jeans and Cooke³ estimated that 2.89 per cent of the babies born in St. Louis had prenatal syphilis and that while the Negroes represented but 9 per cent of the population they contributed one half of the cases of syphilis in infancy. Probably there is an incidence of from 15 to 20 per cent of prenatal syphilis in various stations of society of the United States. The highest

Fig. 2—Severe prenatal syphilis extensive ulcerocrustaceous lesions around the mouth

incidence seems to be found among the Negro race. This is easily understandable, when Vonderlehr⁴ has found the incidence of syphilis in the Negro race in the South to run from 20 to 35 per cent. Jeans and Cooke reported Vedders' study of a hospital group of pregnant women in which more than 7 per cent of the white women were found to be definitely syphilitic and 16 per cent probably syphilitic. In a like group of Negro women the respective percentages were 19 and 31. In a group of white soldiers 8 per cent were undoubtedly syphilitic and 16 probably so, while in a like group of Negro soldiers the percentages were 22 and 36 respectively.

Under such circumstances the death toll is bound to be great. Jeans said (page 99) 'Twenty-five per cent or more of the pregnancies in syphilitic families result in miscarriages or still births'. He estimated that fetal death was at least twice as frequent in syphilitic as in nonsyphilitic families. The infant mortality is much higher when there is syphilis. It formerly ran as high as from 40 to 95 per cent. Conservatively it was 75 per

Fig. 3—Interstitial keratitis and rhagades at the corner of the mouth (courtesy of Dr. Robert Stecher)

cent before the days of arsphenamine, and it is probably from 20 to 30 per cent even now. Since the wider adoption of arsenical salts and of bismuth preparations in the treatment of syphilis the incidence seems to have fallen off sharply.

ETIOLOGY AND PATHOLOGY

In 1905 Fritz Schaudinn, working in Hoffmann's laboratory, discovered the germ of syphilis while hunting for a totally different organism reported to be the cause of the disease. He gave it the name *Spirochaeta pallida*, later changing its name to *Treponema pallidum*. Either term may be used. The organism is not particularly difficult to see with the darkfield illuminator in the mucocutaneous syphiloderm of the new-born babe. At autopsy on such babies it is observed in enormous numbers in the liver, spleen, lungs and kidneys when the silver impregnation method of staining is used. There has been much discussion as to the time at which the fetus is infected and as to the method of infection. Even today there is a school that believes it to be possible for the infection to take place by way of the male sperm. This brings up the point of view of the great Ricord of Dijon and of others that the fetus is thus infected and later infects the mother—the so-called "choc en retour" of the French school. The discovery of *Spirochaeta pallida* has undoubtedly done much to blast this point of view even for physicians who believe in a granular stage of the organism. Moreover, if an ovum were penetrated by a spirochete as well as by a sperm cell, it would undoubtedly succumb at once for it is well known that the fetus has no immunity against the infection. Further *Spirochaeta pallida* has not been observed in the fetus before the fifth or at the earliest the fourth month of pregnancy. As Hoffmann so convincingly pointed out if there were a generative infection the organisms would be expected to develop so rapidly in the fetus that they would be easily demon-

⁴ Vonderlehr, R. A. Venereal Disease Information.

strated in the first months of the pregnancy. The mother then it must be concluded, is first infected, and by the diaplacental route the disease is transmitted to the fetus around the fifth month. Naturally with a later infection of the mother it would be even later. In fact, cases are seen in which the mother's infection takes place so late that the symptoms in the child do not show up until several weeks after birth. Hoffmann would use the term "syphilis connatalis" for such cases.

Fig. 4—Late prenatal syphilis, complete destruction of the nose, eyes and upper lip.

Not every syphilitic mother will transfer the disease to her unborn child. According to Kassowitz's law there will be progressively less chance of transmission as her disease gets older. To illustrate, there was a woman of the moron type at the Cleveland City Hospital with syphilis of the central nervous system of several years' duration. She had successive miscarriages followed by a syphilitic stillbirth and then by the birth of a living, syphilitic child. Early in life the child acquired syphilitic paraplegia. The patient by an order of court was then sterilized. Every syphilitic mother as the infection ages has showers of spirochetes in the blood stream, and it is at such times that an infection would take place if the mother were pregnant. It is for this reason that a syphilitic mother may even bear a syphilitic child, then a normal child and again a syphilitic babe. Even the rare contingency is encountered in which with twins of the double ovum type one placenta and child are infected and the other normal (Jeans). In other words, only rare spirochetes were circulating in the blood stream, and by chance the placenta of only one child was infected. However, on account of this occasional shower of spirochetes in the blood of the syphilitic woman, it should be a hard and fast rule that every syphilitic woman should be treated through every pregnancy. She might be unable to infect by contact, but the intimate association of fetus and mother may be likened to a blood transfusion. The experience of the Scandinavian school, of the Cooperative Clinical Group,* of Findlay,⁶ of Turner and McKelvey⁷ and of others has been almost uniformly that if the syphilitic mother is treated with arsenicals and with bismuth or mercury compounds throughout the pregnancy a normal child will be born. On the other hand, Boas and Gammeltoft⁸ have shown that as long as the syphilitic woman is capable of con-

ceiving one may find cases of syphilis if she receives no treatment. They have observed such cases even twenty years after infection.

The pathologic changes in the child and the placenta are characteristic. The placenta is larger than usual and has thickened rather avascular villi. In some cases it reveals little and yet the child shows plenty of positive evidence. At autopsy the spirochetes are observed in large numbers in the liver, spleen, kidneys, adrenals, heart muscle, bone marrow and testes. Diffuse fibrosis is seen in the various organs, particularly the lungs, pancreas, heart and adrenals. The liver may show areas resembling gummas but which are infiltrated with enormous numbers of spirochetes. There are extensive endovasculitis and perivasculitis. Hoffmann expressed the opinion that the greatly increased number of spirochetes in the fetal tissues is compared to the number in the maternal tissues is to be explained by a lack of immunity on the part of the fetus as compared to the mother and to a lack of oxygenation in the fetus. *Spirocheta pallida* is anaerobic. One of the great changes found in the fetus is the involvement of bones which is recognizable even before birth by x-ray examination. There is extensive osteochondritis of the long bones, so called Wegner's disease of the bones. The line of ossification at the end of the bones, instead of being a thin regular, pearly gray line, is an irregular, thickened zigzag yellowish band. There may, in severe cases even be complete separation of the epiphyses as the result of a fracture in this zone. In these cases there may also be periostitis, e.g., in the phalanges or small bones. Later in life diffuse osteitis may appear, as in the "saber shin." Later in life too there is a tendency to gummas involving bones in various areas, such as the nasopharynx, hard palate and inner end of the clavicle. These are typical granulomas. Involvement of the central nervous system consists of vascular disease with meningo-arteritis and encephalitis. Parenchymatous changes are associated with juvenile dementia paralytica.

CLINICAL PICTURE

For convenience the clinical picture may be divided into early and late manifestations.

The early manifestations of the disease correspond to the secondary stage of acquired syphilis. Ordinarily they show up some weeks after birth. If they are seen at birth the case is usually very severe. It has been well said that prenatal syphilis can ape any of the characteristics of acquired syphilis and then some more. This is certainly true outside of cardiovascular manifestations. Aortitis, aortic insufficiency and aneurysm are not encountered in cases of prenatal syphilis. The face of the babe often looks strikingly like that of a senile little old man (fig. 1). The child is restless, cries feebly but frequently and has snuffles and a reddish brown or coppery eruption most frequently on the palms, soles and diaper area. These may be sharply defined macular, papular, crusted and scaly lesions. Rarely nowadays there is a bullous eruption of these areas. In severe cases the eruption may even be generalized, and around the mouth (fig. 2) will be noted papulocrustaceous radiating infiltrates with moist

papules and ulcerations extending from the insides of the lips outward. Rarely moist papules will be found around the genitalia and between the buttocks. In some cases the fingers may show perionychitis characterized by reddish crusts. It is comparatively simple to isolate *Spirochaeta pallida* with the dark field from the perionychium, from the rhagades and from moist papules or bullae. General examination will reveal an enlarged liver, perhaps down to the level of the umbilicus, and an enlarged spleen. The child may show a diffuse, shiny, ham-red, slightly thickened eruption of the palms and soles which is almost pathognomonic.

Disease of the bones will be found in a fair percentage of the cases, consisting of thickening at the end of the long bones, e.g., the radius and ulna. Owing to pain the child holds the limb as if it were paralyzed, this is Parrot's pseudoparalysis. X-ray examination will reveal the characteristic epiphysitis. Periostitis may also be encountered and occasionally dactylitis. The child may suffer from convulsions or have true paraplegia, and lumbar puncture will reveal involvement of the central nervous system.

LATE PRENATAL SYPHILIS

There is a later stage of prenatal syphilis, as of acquired syphilis, in which the disease has more of a tendency to localize itself to certain parts or organs. In the cooperative group study⁹ of 1,010 patients under observation or treatment for two years or more, approximately one third suffered from parenchymatous or interstitial keratitis, 12 per cent had involvement of the central nervous system and 7.2 per cent had involvement of bones and joints.

Interstitial keratitis may appear at any time from the first four or five years of life to the age of 20 or 25. A fair proportion of the patients are seen in the period from puberty to the age of 18 or 20 (fig. 3). The cornea has a diffuse ground glass appearance in contradistinction to the sharply defined phlyctenules seen in tuberculous persons. There are extreme accompanying photophobia and lacrimation and circumcorneal injection due to the prominence of the ciliary vessels. In fact, these vessels may even invade the cornea, the "salmon patch." In severe cases there may be accompanying iritis, changes in the choroid and peculiar opacities in the vitreous. It is not uncommon for the second eye to be involved, especially when therapy has been neglected. Rarely does ulceration take place in cases of parenchymatous keratitis. Chorioretinitis reveals itself with localized or generalized blackish spots interspersed with yellowish red areas distributed over the surface of the retina.

Late involvement of the bones is seen most frequently in the form of diffuse osteitis or in a peculiar chronic form of hydrarthrosis of the joints first described by Clutton and spoken of as Clutton's joints. The knees are most frequently affected. The great Fournier called attention to a not uncommon syndrome of interstitial keratitis and chronic painless swelling of the knee joints. Unfortunately, its true cause is all too often overlooked. Osteoperiostitis is a diffuse hyperplastic process most often affecting the tibia. The periosteum is first affected, and secondarily there is thickening from new bone laid down.

Gummas may affect the bony structure anywhere but are found most frequently over the tibia, the skull, particularly in the bones of the nasopharynx, the bones

of the upper extremities, and the inner insertion of the clavicle. Trauma has an important role in the production of these lesions. Hutchinson called attention to the saddle nose due to destruction of the bones of the nose (fig. 4).

Gummas may affect soft parts as well as bony structures. Gummatous lesions occur not only in internal structures, e.g., the liver, but in the throat and over the skin. Nowadays it is somewhat uncommon to see the serpiginous ulcerocrustaceous syphiloderms observed in a past generation. Occasionally one encounters gummosis dactylocystitis.

One of the most distressing accidents of late prenatal syphilis is deafness. It may be mild or total. It may come on slowly or at a certain stage progress with great rapidity. If it has progressed very far, it does not seem to respond well to therapy. Naturally it is aggravated if acute lesions and old syphilitic scars are present in the nasopharynx. It affects the sexes about equally and usually reveals itself from the age of 6 or 8 years to the age of 20 or 25. Alexander¹⁰ found that the components of the Hutchinson syndrome were not always equally evident. In 25 per cent of the cases all three symptoms, deformities of the eyes, ears and teeth, were noted. Changes in the internal ear and deformities of the teeth were present in about 10 per cent, involvement of the eyes and ears in 40 per cent and involvement of the internal ear alone in 25 per cent. Cases in which congenital syphilis affects the hearing are of three types: (1) isolated involvement of the eighth nerve, (2) labyrinthine disease and (3) a combination of the two. On the whole, this is one of the most difficult problems to be met in prenatal syphilis.

Medicine is above all indebted to Jonathan Hutchinson¹¹ for proper orientation regarding changes in the second teeth seen in prenatal syphilis. The Fourniers, father and son, have likewise done much to emphasize the important diagnostic side of the disease. The teeth on which Hutchinson laid greatest stress are the upper central incisors. The teeth are narrowed and somewhat smaller than normal, are bowed out on their sides, and show a central depression of the cutting edge due to hypoplasia of the middle lobe. While the other incisors, especially the lower ones, may be affected, Hutchinson advised that there would be less error in the diagnosis if attention was confined to the two upper teeth, (fig. 5).

Another tooth¹² is about as frequently involved as these, the first, or six year, molar, often called the Moon molar, Fournier's tooth, or the "mulberry molar." The grinding surface of the molar is roughened and has three or four small projections covered with enamel—the cusps. Owing to the syphilitic hypoplasia, they are closely grouped, and the enamel slopes outward from this chewing surface to the neck of the tooth, which is of normal size. The tooth has an almost collar-like atrophic process. It usually decays early.

It must be remembered that hypoplasia affecting the teeth may have numerous other causes e.g., rachitis, acute infectious diseases and other severe illnesses. In these cases, however, there is usually general involvement of all the teeth and the picture is quite different. The Hutchinson teeth and the mulberry molar are looked on as pathognomonic of prenatal syphilis, but

in case of doubt other stigmas of the disease should be looked for and will usually be found. However, in case of doubt it should always be remembered that practically 100 per cent of persons with prenatal syphilis show a positive Wassermann reaction of the blood.

THE WASSERMANN REACTION IN CASES OF PRENATAL SYPHILIS

The query is often raised as to the value of the Wassermann reaction of the cord blood. Rietschel said that Brunner found 18 per cent of nonspecific reactions in his series of cases. Kiukenberg put the figure as high as from 30 to 55 per cent. Boas and Thomsen in two of eighty-eight cases found the Wassermann reaction of the cord blood negative when it turned out that the child had syphilis. Turner and McKelvey, working in Moore's clinic, have shown that too much stress must not be laid on the test of the cord blood. Sufficient "reagin" from the mother may be present in the new-born babe to make a positive reaction even though later the child is found to be normal. Again, a child with a negative reaction may later be found to have prenatal syphilis. However, as Moore⁷ puts it, a child with a negative Wassermann reaction of the cord blood is five times as likely to be normal and only one-fifth as likely to acquire other evidence of congenital syphilis as one whose Wassermann reaction of the cord blood is positive. A Wassermann test of the blood at the age of from 3 to 6 months and thereafter will give positive results in almost 100 per cent of cases of prenatal syphilis, and the fastness of the reaction is renowned—even despite therapy. This is so much the case that syphilologists and public health authorities urge the routine use of the Wassermann test of the blood on all children at the age of 1 year and at school age. Thereby latent prenatal syphilis may be discovered, and through treatment the later devastating crippling effects of the disease may be arrested.

INVOLVEMENT OF THE CENTRAL NERVOUS SYSTEM IN PRENATAL SYPHILIS

A not uncommon involvement in prenatal syphilis is that of the central nervous system. It seems to be somewhat more frequent in the earlier years of life than later. Hoffmann suggested that the reason it is not found so frequently later is that the patients die. An incidence of from 20 to 40 per cent has been quoted by Stokes. Jeans and Cooke found neurosyphilis in two fifths of white infants up to the age of 2 years—active in one twelfth of all white syphilitic infants. Of older white children, one sixth had serious neurologic lesions. The incidence is not so high in Negro children. According to Jeans and Cooke's experience syphilitic meningitis is most frequently found in infants. The patients give evidence of pressure symptoms: the fontanel is tense, acute hydrocephalus may be present, and convulsions may occur. Naturally the spinal fluid shows the changes usually observed in cases of meningitis in which the cell count is high and the Wassermann reaction positive. Paralysis of various types is also seen in these young patients, e.g., monoplegia, paraplegia and hemiplegia. With syphilitic meningo-arteritis, such changes are to be expected, as well as occasional paralysis of the cranial nerve. With deeper parenchymatous involvement of the brain tissue, juvenile dementia paralytica is encountered. The symptoms may show up at any time from the age of 5 or 6 years to 20 or 25. In cases in which there is involvement of the posterior column of the cord, the picture of tabes dorsalis presents itself, often with optic

atrophy. Tabetic dementia paralytica of the juvenile type is probably the most unfortunate complication of prenatal syphilis.

SYPHILIS IN THE THIRD GENERATION

Is it safe for the person with prenatal syphilis to marry? Certainly there is no possibility of a man transmitting the disease to his wife or to the next generation. It is probably true that under certain rare circumstances, if the person acted as a donor in a blood transfusion, the disease might be transmitted. This is the problem that arises with the woman who has prenatal syphilis: ordinarily such a person has no organisms in her blood stream. The spirochete, of low vitality and activity, will be observed only sparingly in lymph nodes and perhaps in bone marrow. There is a slight chance that she might transfer the disease to the fetus—it is very slight. Perhaps such persons should receive some antisiphilitic treatment through their pregnancy if they have not been adequately treated in the past.

DIFFERENTIAL DIAGNOSIS

In the average case of early prenatal syphilis the reddish brown or coppery red eruption on the palms, soles and buttocks, perhaps accompanied with snuffles and with radiating superficial ulcerations around the mouth, should suggest to the physician the possibility of prenatal syphilis. In some cases the diffuse, shiny, leathery, brown-red eruption on the palms and soles is almost pathognomonic. If it is bullous, one may be forced to consider a differentiation from bullous impetigo or so-called pemphigoid of the new-born—due to the streptococcus or the staphylococcus. However, the bullous syphilitic eruption is in a sick child and is too diffuse for an ordinary local infection, and the physician should remember that always, in case of doubt, he has a "sheet anchor to windward" in the Wassermann reaction of the blood, which will practically always be strongly positive. Some of the later manifestations of the disease are more likely to be confusing. The child from 8 to 12 years of age with chronic hydrarthrosis of the knees and perhaps with a suggestive Hutchinson's tooth, or with a suggestive diffusely steamy cornea, should cause one by all means to remember the dictum when prenatal syphilis is suspected to take a Wassermann test of the blood. Likewise, there are certain vague cases of early deafness, not associated with acute infectious disease in which syphilis should be kept in mind. Moreover, in any case of eye trouble in the child and in cases of suspected disturbance of the central nervous system, in addition to a careful physical examination, take a Wassermann test of the blood.

TREATMENT OF PRENATAL SYPHILIS

The best treatment of prenatal syphilis is, after all prophylaxis. As long ago as 1923 Almkvist¹³ showed that if the pregnant syphilitic mother received plenty of arsenical therapy and mercury throughout her pregnancy, generally a normal child would be born. He advised treating every syphilitic mother through every pregnancy, using continuous therapy. Strandberg¹⁴ in 1922 proposed the dictum that it is probably best to treat every syphilitic woman through the pregnancy without regard to the age of the infection or to earlier treatment. Ohman¹⁵ treated fifty syphilitic women

13 Almkvist, Johan. Prophylaxis of Congenital Syphilis. *Acta F. Scandinav.* 59: 1-47, 1923.
14 Strandberg, J. *Acta dermat. venerol.* 3: 469, 1922.
15 Ohman. *Acta dermat. venerol.* 5: 262, 1924.

with arsphenamine and mercury in pregnancy and watched the children for at least two years. Only seven children had syphilis, and their mothers had had poor, irregular treatment through their pregnancy. The other forty-three mothers had normal children. Most of these mothers had previously, after no treatment or only a little mercury, borne a series of syphilitic children. Adams¹⁶ and Findlay,⁶ in England, likewise expressed the opinion that the pregnant syphilitic woman should be treated throughout the pregnancy. This is the consensus of Jeans and Cooke,³ Stokes,¹⁷ Moore⁷ and McCord,¹⁸ in this country. Moreover, the Cooperative Clinical Group arrived at the conclusion that "the syphilitic mother should be given early and adequate treatment throughout every pregnancy whether her Wassermann blood test is positive or negative." Treatment practically assures a living child, free from syphilis.

On the other hand, if the child is born with prenatal syphilis, it is well to start him at once on arsenical treatment, using neoarsphenamine, from 0.01 to 0.015 Gm per kilogram (about 2 pounds), as a subfascial injection under the scalp in the parietal region. Jeans said that it is rare for a skilful clinician to be forced to use any but intravenous therapy, i. e., injection into the jugular vein. The drug is dissolved in 2 cc of distilled water. Moore preferred sulfarsphenamine, from 0.010 to 0.015 Gm per kilogram, the drug to be administered intramuscularly into the buttock in a concentrated solution. Ordinarily a course of eight weekly injections of either preparation is employed. It is immediately followed by a series of weekly intramuscular injections into the buttock of a preparation of bismuth, e. g., oil suspension, bismuth salicylate 2 mg per kilogram. Courses of the two drugs may be alternated until a year's therapy has been completed—about twenty-five injections of each preparation. If the Wassermann reaction is still positive at the end of the year, further treatment for six months or a year is in order, especially if the spinal fluid shows evidence of involvement of the central nervous system. In fact, in the latter case, further treatment may even be necessary. Some doctors occasionally use mercurial ointment, 50 per cent, in the form of 1 Gm put on the inner surface of the binder every day, in place of the injections of bismuth. The amount absorbed is somewhat problematic (Smith¹⁹).

With an older group of children, from 6 to 8 years, are found osteitis, periostitis, interstitial keratitis and involvement of the central nervous system. Here arsenical preparations can be administered intravenously, and it is wise to use alternating courses of arsenic and bismuth compounds with no rest periods between courses. Potassium iodide is also indicated in all such cases unless acute interstitial keratitis is present.

With an older group, around puberty, interstitial keratitis, eighth nerve deafness and involvement of the central nervous system are the great problems. All three require the care of an expert and will simply be mentioned here. Heavy arsenical therapy, local measures and foreign protein therapy seem to be of greatest value in cases of interstitial keratitis. Potassium iodide

may be used in chronic cases. In resistant cases, use should be made of malaria or heat cabinet therapy. As in many other phases of syphilis, it will be found that the child adequately and vigorously treated for prenatal syphilis in the early years of life will not be so disposed to later relapse with interstitial keratitis. Involvement of the eighth nerve is extremely resistant to therapy, and the results many times are poor. Children with resistant involvement of the central nervous system, certainly children from 5 years upward, should have the benefit of malaria therapy followed by further arsenical and bismuth treatment. It is not wise to use trypanamide in little children, owing to difficulty in eliciting effects on the optic nerve. While malaria will often stop the progress of juvenile tabes or the tabetic form of dementia paralytica, it too often leaves in its wake simply a spinal animal. However, it is worth the trial in the hope that something will be left.

It is to be hoped that a utopia will be arrived at where all maternal syphilis will be diagnosed early and treated thoroughly, so that prenatal syphilis, like other preventable diseases, will be a thing of the past. May that time arrive swiftly.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary

AUREX HEARING AIDS ACCEPTABLE

Manufacturer: Aurex Corporation, 2400 Sheffield Avenue, Chicago

Two Aurex Hearing Aids, one energized by conventional electric power and one by battery, are semiportable, weighing about 5 and 7 pounds respectively. The power-operated instrument can be used for small group gatherings. This unit works on either alternating or direct current, 115-120 volts. All controls and metal parts are insulated from the power circuit. Four tubes are employed, one of them being a rectifier. The firm claims that all component parts used have rated capacities greatly in excess of requirements. Current consumption is 30 watts.

Each instrument has two controls. One control regulates the volume from zero to maximum, the other control regulates tone so that within a certain range either high or low tones may be emphasized. It may be equipped for either air or bone conduction. As

Aurex Hearing Aid

many as forty phones may be operated from the single instrument. Distributing fixtures for this purpose are available.

The special "Aurex" double compensating phone head-set, supplied for school children and for certain individuals, is a feature permitting the adjustment of each phone so that a difference in the sensitivity of the two ears may be compensated. This uses fully the remnant of hearing in both ears and usually results in much better hearing.

The battery-energized hearing aid consists of a microphone and amplifier of three tubes. A special condenser microphone is used. This modulates a high frequency oscillating circuit which is amplified and demodulated and the audiofrequency component is then amplified and delivered to the phone. In designing this amplifier, the firm claims, attention has been given to the output of the phones as recorded by sound pressure response curves, and compensations within the amplifier made to give, as closely as possible, a straight line output charac-

17 Stokes John H. Modern Clinical Syphilology. Diagnosis Treatment Case Studies ed 2 Philadelphia W. B. Saunders Company 1934 p. 1266.

18 McCord J. R. Prenatal Treatment of Syphilis. Some Results of Antisyphilitic Treatment in a Series of 519 Pregnant Syphilitic Colored Women. *Am. J. Syph.* 16: 78-82 (Jan.) 1932.

19 Smith F. R. Jr. Congenital Syphilis. Results of Treatment in Children. *J. A. M. A.* 105: 409-411 (Aug. 10) 1932.

teristic. There is a tone control for emphasizing the pitch of the instrument to suit the user

This hearing aid employs a self-contained battery, which is said to last from fifty to seventy hours of actual use

The units were investigated by several specialists appointed by the Council. They reported that these instruments were satisfactory, provided one keeps their limitations in mind. The chief limitation lies in the fact that they are not portable hearing aids that may be worn attached to one's clothing but are suitable for meetings, conferences and other places where one can "plug in" or find a resting place for the semiportable battery unit

In view of the foregoing favorable report, the Council voted to include the Aurex portable hearing aids in its list of accepted devices

MAJESTIC ULTRA SHORT WAVE UNIT ACCEPTABLE

Manufacturer Majestic Surgical Instrument Company, 2608 North Cicero Avenue, Chicago

This Majestic Short Wave Unit is recommended for medical and surgical uses in the office or hospital. It is a portable model, weighing 30 pounds complete with carrying case. This may be fitted into a walnut finished mobile cabinet. The

Majestic Ultra Short Wave Unit

electrosurgical currents for coagulating, desiccating and cutting are of sufficient intensity for office practice. The wavelength is approximately 75 meters.

A two-tube push-pull circuit is employed. The parts used are of standard manufacture. The unit is fused against overload or a short circuit. A millimeter, calibrated for a 5,000 milliamperes scale, is utilized.

The input at full load is approximately 500 watts. The output under the same conditions, as measured by a lamp load and the photoelectric cell, is approximately 175 watts.

The transformer temperature rise and temperature at different levels inside the cabinet are within the limits of safety prescribed by the Council.

The firm submitted evidence on the heating ability of the unit as observed in the living human thigh. Six tests were made with the cuff technic. Two healthy male medical students, weighing 150 and 180 pounds respectively, were the subjects. The temperature observations were made by means of a Leeds and Northrup potentiometer and hypodermic thermocouples introduced into the thigh by a cannula. The thermocouple was calibrated in degrees Fahrenheit against a Bureau of Standards certified thermometer.

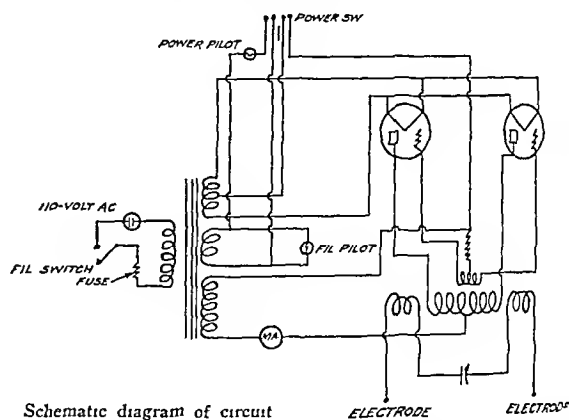

Averages of Six Observations, Cuff Technic

	Deep Muscle	Oral
Initial	99.9	98.6
Final	106.5	98.9

A trocar placed in a hard rubber cannula was inserted at a right angle to the thigh and straight down into the muscle tissue until the instrument was at an approximate depth of 2 inches or until the femur was encountered. The trocar was removed, the rubber cannula being left in situ. Initial temperatures were taken and then each subject was submitted to a twenty minute application of maximum current intensity consonant with skin comfort. The highest temperature attained was recorded as final in each instance. Oral temperatures also were taken.

The technic of application included the use of double cuffs, measuring 24 by 3 inches. These were spaced equidistant from the cannula and 7½ inches apart, center to center. The electrodes needed no extra spacing but a towel was placed between the skin and cuff for purposes of cleanliness. The averages of six observations by means of this technic are given in the accompanying table.

The unit was investigated in a clinic acceptable to the Council. It was reported to be satisfactory in heat production. Burns may occur with this type of machine but are less likely to occur than with the conventional diathermy. These may be avoided by taking ordinary precautions.

Schematic diagram of circuit

In view of the foregoing favorable report on the clinical behavior of the Majestic Short Wave Machine, the Council on Physical Therapy voted to include it in the list of accepted devices.

ALOE PORTABLE SHORT WAVE DIATHERM ACCEPTABLE

Manufacturer A S Aloe Company, 1819 Olive Street, St. Louis

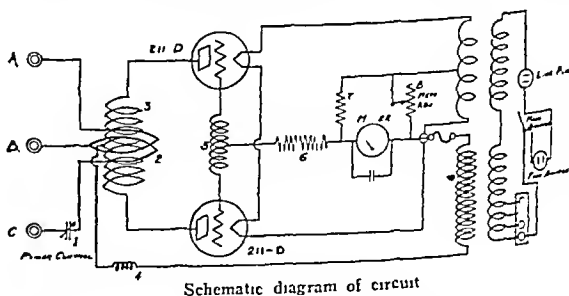

This Aloe Portable Short Wave Diatherm is designed for medical and surgical use. It is essentially the same as the Council accepted Aloe Short Wave Diatherm (THE JOURNAL, Jan 11, 1936, p 122) except for the addition of a surgical outlet. It is equipped with pad and cuff electrodes and surgical attachments. The wavelength is about 15 meters. The shipping weight is approximately 75 pounds.

The circuit consists of a conventional two-tube oscillator push-pull type. The input power required is approximately 540 watts. The transformer temperature rise and that in the cabinet at various levels is within the limits of safety prescribed by the Council.

The investigations of the Council showed that there was very little difference in construction between the new model and the one previously accepted. This unit was operated under actual clinical conditions and was found to render satisfactory

Aloe Portable Short Wave Diatherm

Schematic diagram of circuit

service. Burns may occur with this unit as with other short wave units but may be avoided by taking ordinary precautions. It is stated that they are less likely to occur than with conventional diathermy.

In view of the foregoing report, the Council on Physical Therapy voted to include the Aloe Short Wave Diatherm in its list of accepted devices.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C BING Secretary

PRIDE OF THE FARM TOMATO JUICE

Manufacturer—E Pritchard, Inc, Eagle St, Bridgeton, N J

Description—Canned tomato juice seasoned with salt retaining in high degree the natural mineral and vitamin values

Manufacture—Vine-ripened New Jersey tomatoes are graded by U S government inspectors, washed, hand sorted, spray washed and blanched Juice is mechanically extracted, transported to covered tanks and heated to 88 C in five minutes Salt is added Hot juice is automatically filled into cans, which are then sealed and processed at 100 C for twenty minutes Thirty minutes is required for the entire process Whenever stirring is necessary, cylinders or agitators are operated at low speed to prevent incorporation of air All lines and containers are porcelain lined, nickel or stainless steel

Analysis (submitted by manufacturer)—Moisture 94.1%, total solids 5.9%, ash 1.1%, sodium chloride (NaCl) 0.6%, fat (ether extract) 0.2%, protein (N \times 6.25) 1.0%, crude fiber 0.2%, sucrose nil, reducing sugars as invert sugar 3.1%, carbohydrates other than crude fiber (by difference) 3.0%, acidity as citric acid 0.4%, *pH* value 4.25, tests for known preservatives nil, tests for aniline colors nil

Calories—0.18 per gram, 5 per fluidounce

Vitamins—The product contains 17 mg of cevitamic (ascorbic) acid per hundred cubic centimeters (3.4 International units per cubic centimeter)

Claims of Manufacturer—This tomato juice is a good source of vitamins A and B and an excellent source of vitamin C, for infant feeding and general table use

VALORA BRAND VALENCIA ORANGE JUICE 100% PURE

Manufacturer—Santa Barbara Citrus Juice Company, Inc, Orange, Calif

Description—Canned, pasteurized California Valencia Orange Juice practically equivalent to fresh orange juice in vitamin C content

Manufacture—Selected tree ripened fruit is washed, inspected, automatically cut in halves and reamed by hand The juice is strained, deaerated vacuum filled into cans, vacuum sealed, pasteurized and immediately cooled

Analysis (submitted by manufacturer)—Moisture 85.2%, total solids 14.8%, ash 0.5%, fat (ether extract) 0.1%, protein (N \times 6.25) 1.2%, reducing sugars (as invert) 6.8%, sucrose 3.8%, crude fiber 0.04%, carbohydrates other than crude fiber (by difference) 1.3%, titratable acidity as citric acid 1.2%, *pH* 3.56, vitamin C (titration) 40 mg per 100 cc (840 International units)

Calories—0.6 per gram, 17 per ounce

Vitamins—A rich source of vitamin C

HULBURT'S BRAND CALIFORNIA LEMON JUICE

Manufacturer—Hulburt's Fruit Products, Inc., Los Angeles

Description—Canned lemon juice retaining in high degree the natural vitamin content

Manufacture—A standard grade of tree ripened California lemons, selected for ripeness, acidity and perfection, are automatically washed halved and reamed by hand on juice extracting machines The juice is strained, filled into special lacquered cans flash pasteurized and chilled Air is excluded as much as possible

Analysis (submitted by manufacturer)—Moisture 91.4%, ash 0.22%, fat (ether extract) 0.06%, protein (N \times 6.25) 0.4%,

sucrose 0.4%, reducing sugars (as invert sugar) 1.7%, crude fiber 0.05%, carbohydrates other than crude fiber (by difference) 2.0%, titratable acidity as anhydrous citric acid 5.8%

Calories—0.10 per gram, 3 per fluidounce

Vitamins—1 cc of lemon juice contains 9 International units of vitamin C

WEGNER NEW YORK STATE BRAND FANCY APPLE SAUCE

Manufacturer—Wegner Canning Corporation, Sodus, N Y

Description—Canned apple sauce prepared from peeled and cored apples with added sugar

Manufacture—New York State winter apples are peeled and cored by machine, trimmed of any blemishes or remaining skins, inspected, forced through slicers into cooking chambers containing an atmosphere of steam, and mixed with sugar The cooked apples are pulped, automatically filled into cans which are hermetically sealed, pasteurized and then cooled

Analysis—Moisture 76.5%, total solids 23.5%, ash 0.2%, fat (ether extract) 0.1%, protein (N \times 6.25) 0.2%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 2.25%

Calories—0.9 per gram, 26 per ounce

ROBIN "FRESHLIKE" BRAND STRAINED UNSEASONED PRODUCTS (PEAS, CARROTS, BEETS, SPINACH, GREEN BEANS TOMATOES, CELERY, APPLES, PRUNES, APRICOTS, AND VEGETABLES WITH CEREAL AND BEEF BROTH)

Distributor—Scudders-Gale Grocery Company, Quincy, Ill

Packer—The Larsen Company, Green Bay, Wis

Description—Respectively strained peas, spinach, carrots, beets, green beans, celery, tomatoes, prunes, apples, apricots and vegetables with cereal and beef broth, prepared by efficient methods for retention in high degree of the natural mineral and vitamin values No added sugar or salt These products are the same as the respective accepted Larsen's vegetables and fruits (THE JOURNAL, Aug 26, 1933 p 675, Aug 12, 1933, p 525, Aug 19, 1933, p 605 July 8, 1933 p 125 July 29, 1933, p 366, Sept 2, 1933, p 779, July 1, 1933 p 35, July 22, 1933, p 282, Aug 10, 1935, p 437, July 4, 1936, p 38, July 22, 1933, p 283)

KINGCO CHOCOLATE FLAVOR

Manufacturer—Doral Food Products Company, Inc, New York

Description—A powdered chocolate flavored mixture, consisting of sweetened malted milk, pasteurized defatted milk, Dutch cocoa, with added American whole egg powder

Manufacture—The ingredients are mixed, dried and filled into containers

Analysis (submitted by manufacturer)—Moisture 4.2%, total solids 95.8%, ash 3.25%, fat (Mojonnier method) 2.7% protein (N \times 6.25) 11.3%, sucrose 48.0%, lactose + 1 H O 12.8%, maltose + 1 H O 2.9%, crude fiber 0.7%, carbohydrates other than crude fiber (by difference) 77.85%, caffeine 0.10%, theobromine 0.47%, milk protein (N \times 6.25) 7.5% lecithin (P O) 0.019%, lecithin (calculated to whole egg solids) 1.8%, lecithin (calculated to whole egg) 6.8%

Calories—3.80 per gram, 108 per ounce

LESLIE BRAND HAWAIIAN PINEAPPLE JUICE

Distributor—Cressey Dockham and Company, Inc, Salem, Mass

Packer—Hawanan Pineapple Company, San Francisco

Description—Canned unsweetened pineapple juice, the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3, 1933 p 1769)

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

PREDISPOSING FACTORS IN THE LATE TOXEMIAS OF PREGNANCY

The search continues unabated for the causative agent of eclampsia, which Zweifel has called "the disease of the theories," and of the toxemic states leading to eclampsia, variously known as preeclamptic toxemia, low reserve kidney, eclampsism or eclamptogenic toxemia. Will a single causative agent ever be found? What part do heredity, diet, climate, race, parity and constitution play in the occurrence of these conditions? Why was the incidence of eclampsia and the toxemic states of pregnancy so greatly diminished in central Europe during the World War? Was it due to the restricted ration, particularly poor in proteins and fats, brought about by the enemies' blockade? Why are the more obese plethoric women and primiparas more susceptible? In how many women with toxemia is there a history of some recent acute process that has not been elicited or, if known, has been disregarded as being too remote to have any possible connection? All these questions may have some bearing on etiology.

The occurrence of eclampsia has undoubtedly been greatly reduced by better antepartum care during the last few decades. Ordinarily eclampsia need not be feared if the patient will cooperate with a competent obstetrician from an early period of her pregnancy. Exceptions will occur, however, and an acute fulminating eclamptic toxemia may at times give little warning. Williams¹ stated that the physician who says that eclampsia need never occur is "either misinformed or careless in the use of words." He cited instances in which eclampsia developed in women who had had normal blood pressures and albumin-free urine the day before. The pathologic conditions leading to the eclamptic explosion were probably in operation but had not made themselves manifest as symptoms.

Peters² recently studied 351 patients with toxemias of pregnancy, excluding the cases of vomiting of early

pregnancy. One hundred and fifty patients had satisfactory records, of these only fifteen had no relevant disturbances preceding their first toxemias. It is safe to assume that at least some of the patients who had inadequate histories had suffered some disease which helped prepare the ground for the toxemia. Forty-two patients with pyelitis or pyelonephrosis were found. Thirty-six other patients, while suffering from pyelitis during pregnancy, developed hypertension or edema, twenty-two showed evidence of renal or vascular disease varying from albuminuria or nephritis to renal calculi, two had preexisting arterial disease manifested in one by hypertension and in the other by chorioretinitis. From the histories alone, from forty-five to forty-seven patients out of 150 had definite renal or vascular disease before the pregnancies in which toxemia first occurred. Approximately 10 per cent of the patients had a history of rheumatic fever or chorea, most of them showing signs of heart disease. Acute respiratory infections preceded the toxemia in sixteen instances. In view of the infectious origin of nephritis and of pyelitis, the possibility that infection plays a significant part in the toxemias of pregnancy should be more thoroughly investigated, although the infectious theory has been discounted during the past few years. In general, the predisposing factors appeared to be renal and vascular disorders and the diseases that cause such disorders.

As to recurrences, at least 41 per cent of the patients developed toxemia in subsequent pregnancies. Eclampsia, as well as the other forms of toxemia, whichever way they may be classified, far from conferring immunity, tend often to recur. Of the total 351 patients, 148 were not traced. One hundred and twenty, or 34 per cent, are either dead or victims of chronic disease, and sixty-nine, or 20 per cent, have had further toxemias. At best, but 46 per cent survive in good health and only fifteen, or 7 per cent, of those traced are free from disease.

The study showed that the usual classification of toxemias of pregnancy based on clinical symptoms may be fallacious and misleading, thus clinical manifestations of eclampsia were observed in patients with pyelitis or pyelonephrosis. "Typical" eclamptic pathologic conditions were disclosed in a hypertensive patient who died of a dissecting aneurysm of the aorta without any clinical symptoms of eclampsia. Often the clinical course of the toxemia is unmistakably that of acute nephritis. Liver damage varying from transitory jaundice to acute yellow atrophy may occur during pregnancy, but it can hardly be the cause of the hypertension and vascular disturbances characterizing toxemias. In this connection Bell,³ in performing necropsies on ten women who died from eclampsia, found a great variety of lesions in the liver but nothing typical of all. Passive congestion, localized infiltration, acute yellow

¹ Williams J. W. *Obstetrics* ed. 6 New York D. Appleton & Co. 1931 p. 644.
² Peters J. P. *J. Biol. & Med.* 9: 311 (March) 1937.

³ Bell J. W. *Am. J. Obst. & Gynec.* 12: 792 (Dec.) 1936.

atrophy, infarction, hemorrhagic necrosis and cellular infiltration of the portal spaces were disclosed, but no common condition

Renal or vascular disease in the nonpregnant state may cause hypertension, convulsions, edema and albuminuria, these symptoms developing gradually, but when pregnancy is superimposed the apparently mild disease changes abruptly to a malignant state. The patient who would survive without the pregnancy may be overcome by the added burden.

The basophilic accumulations noted by certain investigators in the pituitary gland in the toxemias of pregnancy have also been found in other patients of both sexes suffering from hypertension due to a variety of causes. The reaction would seem to be the result rather than the cause of the toxemias.

Herrick and Tillman⁴ also studied the late toxemias from a medical point of view (594 cases) and observed that they fell into two groups, the first and smaller being associated with a latent or manifest primary glomerulonephritis, the second and larger with hypertensive vascular disease. In more than half of those still alive after three years, symptoms and signs of one or the other of these conditions were disclosed. Of the eleven necropsies performed, seven showed the changes characteristic of cardiovascular disease with hypertension, and four of those of chronic glomerulonephritis. The authors felt that the distinction between the mild and severe types of late nonnephritic toxemia were of degree, not of kind, and that therefore the terms "low reserve kidney," "recurrent toxemia" and so on were confusing and should be abolished. The pathologic process in the kidneys was considered to be the result of the general intoxication rather than the cause.

As far as the saving of life is concerned, the present methods of treatment are adequate when properly applied, but the injury to the renal and vascular systems is nearly always made manifest in subsequent pregnancies, which cause further permanent damage. Therefore Peters concludes that pregnancy should be prevented in women with such preexisting disease or in those who have had previous toxemias, and terminated on the appearance of symptoms if pregnancy occurs.

That pregnancy under such circumstances should be avoided at all costs is incontrovertible in view of the evidence presented. There may be some disagreement, however, with the dictum that the pregnancy should be terminated on the first appearance of symptoms. Nevertheless the certainly crippling and perhaps lethal effect of another pregnancy presents a problem that calls for the best thought and closest cooperation of the obstetrician, the internist and the pathologist.

SYNERGIC ANTIGENS

Three years ago Burky¹ of the Wilmer Institute of Ophthalmology at Johns Hopkins University reported that intracutaneous injection of staphylococcus toxin into rabbits led to the development of an active immunity against this toxin, accompanied by an acquired hypersensitivity to the nutrient broth in which the staphylococci were grown. Control injections with broth alone did not lead to demonstrable hypersensitivity. Burky assumed, to account for this concurrent hypersensitivity, that the toxin rendered certain immunologically inert broth proteins actively antigenic. Subsequently he combined staphylococcus toxin with lens proteins, rabbit muscle proteins and pollen extracts, all of which are practically nonantigenic when injected into rabbits. Braun,² for example, was unable to produce precipitins against lens proteins, nor could he sensitize rabbits against lens products. Burky found, however, that lens protein broth inoculated with a toxin-forming strain of staphylococcus aureus became actively antigenic. Rabbits injected with the resulting lens toxin complex develop high precipitin titers against lens protein and become actively hypersensitive to these proteins.

Burky also found that rabbit muscle could be rendered strongly antigenic for rabbits by inoculating muscle broth with staphylococci. Ragweed extract was also changed to an active antigen and rabbits injected with the toxin-pollen complex developed relatively high antipollen precipitins. Dusting with pollen caused typical anaphylactic syndromes in these animals. Control rabbits injected with ragweed pollen alone did not develop precipitins or pollen sensitivity.

Swift and Schultz³ of the Rockefeller Institute have extended these synergic studies to other proteins and to other bacterial toxins. They found, for example, that the synergic effects of staphylotoxin on lens proteins are demonstrable when the toxin and proteins are introduced separately "either into the same tissues, with several hours elapsing between injections, or into different veins." From this they conclude that an intimate association of toxin and protein is unnecessary for the synergic effects, the toxin presumably exerting a catalytic or stimulating action on the antibody-forming cells. A somewhat similar hypothetical "synergic conditioning" of antibody-producing tissues was demonstrable with diphtheria toxin, streptococcus toxin and relatively nontoxic horse serum⁴.

The synergic phenomenon of greatest current interest, however, is the alleged stimulation of specific antibody production as a result of intravenous injections with cevitamic acid. Jusatz,⁵ for example, reports

4 Herrick W W and Tillman A J B. The Toxemia of Pregnancy. Its Relation to Cardiovascular and Renal Disease. Clinical and Necropsy Observations with a Long Follow Up. that cevitic acid injected intravenously into rabbits during the immunizing period increases the specific precipitin titer of the blood serum about tenfold, control rabbits being injected with the same protein (horse serum) but without concurrent cevitic acid therapy. Lemke⁶ found that injections with cevitic acid would apparently desensitize hypersensitive guinea-pigs, presumably as a result of stimulation of an antagonistic specific antiprotein immunity. Jungeblut⁷ reports that injections of small doses of cevitic acid into intracerebrally infected monkeys often causes a therapeutic abortion of the paralytic symptoms. In his hands, larger doses of cevitic acid were therapeutically ineffective.

Three years ago, Cooke⁸ of Cornell University Medical College predicted that in time the Burky phenomenon of synergic antigenicity would be recognized as an epoch-making discovery in the field of theoretical and practical immunology. The evidence available today indicates that he was no doubt justified in this prediction of its ultimate clinical importance.

Current Comment

VITAMIN A RESERVES IN HEALTH AND DISEASE

It is important to know accurately the quantity of vitamin reserves available in the human body and whether these reserves may be depleted by diseases other than the known deficiencies. The quantitative estimation of vitamin A in the tissues can be readily made by a strictly chemical method, using the antimony trichloride reaction.¹ Moore and Ellison have employed this method in the analysis of 1,000 adult human livers and approximately 200 livers of children under 15 years of age. The average values obtained in forty cases of accidental death in subjects between 15 and 59 years of age was 220 international units per gram of moist liver. This contrasts with the vitamin A reserves in normal infants up to 3 months of age, which were found to be low—only 17 units. After the first four months the reserves rose to a much higher level, reaching an average value of 130 units between the ages of 4 months and 14 years. This value is still lower than in the healthy adult but may possibly be explained by the relatively greater size of the child's liver. The wide variations found in normal livers make the evaluation of the vitamin A content of diseased livers difficult. The authors nevertheless have grouped their diseases according to the vitamin A level found in the liver. Those diseases with vitamin A reserves above normal (average 300 units) included thyroid diseases of all types (nine cases) and diabetes. These were in adults. In the children, high reserves were invariably found in tuberculosis, although this disease

in adults did not produce a higher than normal hepatic vitamin A reserve. Consistently low vitamin A concentrations were found in the livers of adults dying of nephritis (75 units), peritonitis (75 units), pneumonia (63 units), kidney and bladder infections (19 units) and other infectious diseases. Similar observations were made in the children's group. Since it is obvious that high vitamin A reserves may be attributed directly to dietary factors, these investigators make no attempt to evaluate the etiologic significance of their data.

INFECTIONS WITH ANAEROBIC STREPTOCOCCI

Investigations of the rôle of anaerobic streptococci in disease are relatively rare. Heretofore, according to McDonald and his co-workers,¹ anaerobic streptococci have been recovered from human tissues mainly in cases of puerperal and pulmonary sepsis. The object of their present investigations was to determine the type of lesion encountered in such infections as well as the biologic and agglutinative properties of the organisms recovered, and to study the pathogenicity of anaerobic streptococci for animals. The cases studied occurred between 1931 and 1936 and consisted of those patients coming to necropsy in whom anaerobic streptococci were recovered either from the blood or from the lesions at the time of death. In the twenty-three cases in which these organisms were recovered, some part of the intestinal tract was involved nine times, the lungs primarily seven times, and the meninges four times, in three cases the lesions occurred in various tissues. Abscess of the lung was the most predominant pulmonary lesion in four cases, gangrenous appendicitis with rupture accounted for five of the intestinal lesions. There were three cases in which carcinoma of the large intestine had perforated and produced an abscess. In one case duodenal ulcer had perforated two and one half months previously and had been surgically closed. The four cases in which anaerobic streptococci were isolated from the meninges represented a type of infection on which little has been written. The foci in all four cases were different and represented chronic infections in the nasopharynx, frontal sinus and middle ear, and an infected wound of the tenth thoracic vertebra. The duration of the major symptoms varied from four days to one and one-half years. Microscopically most of the lesions presented the appearance of a nonspecific granuloma. Anaerobic streptococci were recovered in pure culture in eleven of the twenty-three cases. Often they were isolated both from the blood and from the lesion. These facts suggest that they played a significant part in all the cases in which they were present even when other pathogens also were found. They were mixed with aerobes in seven cases and with anaerobes in seven. The strains of streptococci appeared to be morphologically similar with few exceptions. When strains thus isolated were injected into animals subcutaneously, intramuscularly, intraperitoneally or intravenously, no lesions could be produced. Iridocyclitis and meningitis, on the other hand, developed in rabbit-

following direct injection of the anaerobic streptococci. The results of animal inoculations, however, emphasize the fact that such streptococci are virtually nonvirulent for laboratory animals. They are more virulent, it seems, when acting in symbiosis with other organisms. The meninges are more vulnerable even to organisms of low virulence than most other tissues. For that reason it seems probable that, in the four cases of meningitis, anaerobic streptococci alone were responsible for the lesions.

IDENTIFICATION OF FOODS CAUSING DISTRESS

Individuality in the prescription of diets is often necessary because of idiosyncrasies to particular foods. Alvarez,¹ in a recent discussion of this subject, states that the physician will be particularly interested in searching for offending articles of diet when the patient observed suffers occasionally from hives, hay fever or asthma, or when the patient has relatives who suffer with allergic disorders. One must be suspicious of food sensitiveness also when the symptoms are largely those of a sensitive colon. Several methods are available for determining the offending foods. Thus, when the suspected symptoms come in attacks at intervals of weeks or months the cause can often be found by making each time a written record of all the unusual foods not eaten every day but consumed in the twenty-four hours preceding the upset. After three or four attacks the record should be examined to see whether there was any one food that was eaten just before each upset. Subsequently relief should be obtained when the food is omitted and an attack should occur when the food is again eaten. When, however, the distress is present after almost every meal the problem of finding the offending food or foods must be simplified by reducing the number of possibilities. If, on omission of all food for a few days, the distress continues, it is clear that food could have no causal relationship. If, however, the distress ceases promptly, then the patient could try one new food each day, keeping the good ones and rejecting the bad ones, until he has a sufficient but non-distress causing dietary. Even when a patient obtains prompt relief on an elimination diet, it sometimes happens that, after the patient returns to work and the burden of strain, annoyance and worry, some of the symptoms return. In many persons, unfortunately, indigestion, headache and abdominal pain can be produced not only by eating certain foods but also by fatigue, nervousness and worry, or combinations of these. Sometimes, however, after a patient has been at home for a few months it will be discovered that some of the foods which formerly caused trouble can again be eaten in moderation with impunity. For the latter reason, occasional experimentation with forbidden foods should be made and an attempted return to as nearly normal a diet as possible may result. Certainly no one should ever remain for weeks or months on a highly restricted elimination diet, the purpose of the restricted diet is definitely diagnostic and is not applicable for extended treatment.

PHYSICAL RECONSTRUCTION

The benefits of corrective exercises and other measures for improving the health of physically subnormal persons have recently received much study. A report by Capon¹ is based on observations of substandard recruits in the British army. Thirty-three men of deficient physical qualities were enlisted and assembled in the Army School of Training in the fall of 1936. All were townsmen with ages given on enlistment of from 18 to 20 years. All, furthermore, gave the impression of undernourishment and lack of fresh air and exercise, and only one had played games to any extent prior to enlistment. The causes of rejection were under weight six, under chest measurement four, under weight and chest measurement sixteen, under height two, disordered action of the heart one, genu valgum one, hallux rigidus one, hallux valgus one, and scoliosis one. The oral hygiene was good in sixteen, fair in nine and neglected in six, and an average of 1.3 extractions per man was indicated. The diet given these men consisted of the ordinary food supplied to the students of the school, which is of the same quality and quantity as that for the rest of the army, but the cooking was above the average. The exercises were those usual for recruits in the British army but were under the direction of instructors picked because of their special suitability for this work. At the end of the second week a general survey was made to find whether any had reached the required physical standard. Of those previously under weight or chest measurements, ten were already up to the required standards. Furthermore two men, one suffering from hallux rigidus of both feet and one from disordered action of the heart, had become apparently fit for enlistment. At the end of the sixth week it was found that twenty-one men had reached the standard, while six more were just below (only 1 or 2 pounds). The deformities, with the exception of one hallux valgus and one genu valgum, could be said to have disappeared. The average gain in weight had been 6½ pounds, while the greatest individual gain was 12 pounds. The average gain in chest measurement was 1 inch, with the greatest individual gain 2 inches. The results of this experiment, Capon says, are encouraging. Out of thirty-three men, twenty-four were made thoroughly fit in three months. He concludes that young men can be made fit quite easily if the necessary facilities are available. It should be possible, from an army point of view, to give an estimate of those likely to benefit after a period of six weeks' work. Desirable corrections should be taken in hand without delay and applied to the post school age (14 to 18). Most of the postural deformities disappeared or at least improved with strengthening of the muscles. Although the numbers involved in this trial were small, the results do suggest that much may be done even in a short period to counteract the effects of previous poor environment. These observations corroborate the general impression that environment, in the large sense, definitely affects bodily build.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Committee on Syphilis—The state superintendent of public health has appointed the following committee on control of venereal diseases suggested by the Arizona State Medical Association: Drs Hilary D Ketcherside, Phoenix chairman, Howard M Purcell, Phoenix, and William G Shultz, Tucson. Two clinics are to be established, one at Phoenix and one at Tucson according to *Southwestern Medicine*. Each will be directed by a part time physician with a technician to carry out laboratory tests.

ARKANSAS

New Officers of State Board—Dr William A Snodgrass, Little Rock, was chosen president of the State Medical Board of the Arkansas Medical Society at its recent meeting. Dr Lorenzo T Evans, Batesville, vice president and Dr Leonce J Kosminsky, Texarkana, secretary. New members of the board are Dr Eugene A Callahan, Carlisle, succeeding Dr William T Lowe, Pine Bluff; Dr Daphney E White, El Dorado, succeeding Dr Albert S Buchanan, Prescott; and Dr DeVeaux L Owens, Harrison, succeeding Dr William H Mock, Prairie Grove.

CALIFORNIA

Personal—Dr Jacob C Geiger, director of public health city and county of San Francisco, was recently chosen president of the Pasteur Society of Central California. Dr Ernest A Wagner, Los Angeles, has accepted an appointment from the Foreign Mission Board of Seventh Day Adventists as medical director of the denominational sanatorium in Canton, China, newspapers report. He will sail from San Francisco September 4. Dr Howard W Bosworth has been appointed resident and physician-in-charge of the Barlow Sanatorium, Los Angeles, following the sudden death of Dr Munford Smith. Dr Hamilton H Anderson, assistant clinical professor of pharmacology at the University of California Medical School, San Francisco, has been appointed to the staff of the Council on Medical Education and Hospitals of the American Medical Association. Dr Anderson, who will assist in the general supervision of hospitals and medical schools, will become a full time member of the staff of the Council, October 1.

CONNECTICUT

Society News—At the annual meeting of the Connecticut State Dental Association in Hartford recently, the speakers included Drs Sigmund S Greenbaum, professor of clinical dermatology and syphilology, University of Pennsylvania Graduate School of Medicine, Philadelphia, on "Oral Manifestations of Systemic Diseases," and Francis P McCarthy, Boston, "A Clinical and Pathological Study of Oral Lesions."

Personal—Dr Stanhope Bayne-Jones, dean and professor of bacteriology, Yale University School of Medicine, New Haven, has been elected a member of the medical advisory board of the Leonard Wood Memorial (American Leprosy Foundation). Dr Margaret Tyler, associate clinical professor of obstetrics and gynecology, Yale University School of Medicine, New Haven, received the honorary degree of doctor of science at the recent centennial celebration of Mount Holyoke College. Dr Ross G Harrison, Sterling professor of biology, Yale University School of Medicine, New Haven, has been elected a foreign honorary member of the Royal Academy of Medicine of Belgium.

Hospital News—Work began on the new Bradley Memorial Hospital July 1, in New Southington. The facilities of the new hospital will be for the most part used for preventive medicine according to the *New England Journal of Medicine*. Part of the basement and the entire first floor of the two story L-shaped building will be used for a clinical public health service. The top floor will be used exclusively for emergency hospitalization and will contain a complete modern operating suite and a hospital outfit for from eight to ten beds. The building will also contain a venereal disease clinic. Funds for the hospital, which will cost about \$115,000, were left by Mrs Julia A Bradley, who died in 1919. The will stipulated that the hospital must be built within twenty-one years.

GEORGIA

Personal—Dr Russell H Oppenheimer, superintendent of Emory University Hospital and dean of Emory University School of Medicine, Atlanta, has been made medical director of the hospital and Mr Robert S Hudgens, assistant superintendent, has been appointed superintendent. Dr Thomas Oscar Vinson, Macon, assistant health officer of Bibb County, has been appointed health officer of Spalding County with headquarters in Griffin. The Athens-Clarke County Board of Health at a meeting July 1 adopted a resolution commending Dr Wedford W Brown, health officer since 1937. Dr Brown was recently chosen president of the Georgia Public Health Association. Dr John P Kennedy, who has been health officer of Atlanta for thirty-six years, has been elected for another three year term. Dr Herbert F Reading, Durham, N C, has been appointed health officer of the Thomas County Health Department, succeeding Dr James R Dykes, resigned.

IDAHO

State Medical Meeting—The annual meeting of the Idaho State Medical Association will be held in Boise August 30-September 3. Five guest speakers from the University of Minnesota Medical School, Minneapolis, and the Mayo Foundation, Rochester, Minn, will conduct the program, each speaking several times and conducting clinics. Following is the list of speakers and their subjects:

Dr William F Braess, Rochester, genito-urinary tuberculosis, hydro-nephrosis, nephrolithiasis and polycystic kidneys, hematuria—cause and significance, infections of the genito-urinary tract, diseases of the prostate.

Dr Harold E Robertson, Rochester, pathology of kidney lesions, pathogenesis and course of tuberculosis, laboratory diagnosis of tumors, pathologic features of cardiovascular disease, pathology of cirrhosis of the liver, illustrations of prostatic lesions.

Dr Frank J Heck, Rochester, present status of vitamin and hormone therapy, clinical management of nephritis, pernicious anemia and secondary anemias, hypertension and coronary disease, management of jaundice.

Dr Francis W Lynch, St Paul, syphilis including general diagnosis, syphilis, resume of treatment, carcinoma of the skin, dermatitis, including eczema, the purulent skin—scabies—impetigo.

Dr William P Sadler, Jr, Minneapolis, sepsis in obstetrics, toxemia in pregnancy, hemorrhage in obstetrics, spurious pregnancy, alleria, tion of pain in labor.

At the annual banquet Tuesday evening August 31 the guest speaker will be Fay Cooper-Cole, PhD, professor and head of the department of anthropology at the University of Chicago, on "An Anthropologist's View of Race."

ILLINOIS

Another Case of Rocky Mountain Spotted Fever—What was said to be the seventh case of Rocky Mountain spotted fever ever reported to the state department of health occurred in an 8 year old boy at Grafton who had been ill since June 25 according to a newspaper account July 26. After blood specimens showed a positive reaction to the Weil-Felix test the child's parents recalled that he had been bitten by a tick several days before he became ill.

Examination for District Health Officers—The state department of health announces that an examination will be held at Springfield for the purpose of selecting health officers for the Champaign-Urbana health district and the East St. Louis district. Applications must be received by September 15. Blanks may be obtained by writing to the director, Illinois Department of Health, Springfield. Acceptable applicants will be informed by mail as to the specific date of the examination. The determination of qualification for the positions will be based on the standards appearing in appendix A, supplement No 126, the Public Health Program, under title VI of the Social Security Act as published by the U S Government Printing Office, Washington, 1937.

Chicago

Infantile Paralysis in Boy Scout Camp—Camp Owassipp, near Muskegon, Mich., where 250 Chicago boy scouts had been spending a two weeks' vacation, was closed August 16, following an outbreak of infantile paralysis which resulted in the death of one boy and the serious illness of two others. The *Chicago Tribune* reported. The boys will return to their homes, which will be placed under quarantine. So far this month there have been four other deaths and thirty-two cases of infantile paralysis in Chicago as compared with three deaths and twenty other cases of the disease during the first fifteen days of August 1936.

Society Approves Campaign on Syphilis—The council of the Chicago Medical Society at a special meeting July 22 voted to support the campaign against syphilis now under way.

in Chicago to the extent of taking blood specimens. As a part of the drive questionnaires have been released to the public to determine the number of persons in favor of or against taking blood tests for syphilis. The questionnaire reads "In strict confidence and at no expense to you would you like to be given by your own physician a blood test for syphilis?" About 650,000 questionnaires had been issued up to August 16 and the returns at that date showed a ratio of 16 to 1 in favor of the tests. While the work is being carried out by the U. S. Public Health Service, WPA and local health authorities, all statistical information pertinent to the survey will be released through the Chicago Medical Society. A recent appropriation by the city council of \$50,000 will be used to condition the old South Division High School, Wabash Avenue and Twenty-Sixth Street, as a laboratory for social hygiene services and the renovation of a building on the west side for similar purposes is under consideration. It is not the intention to establish additional venereal disease clinics but to standardize and utilize existing clinics and encourage private practitioners to take patients in the small income groups at reduced fees by supplying free drugs and laboratory service. Under the Chicago plan of venereal disease control, a new panel system of records has been worked out whereby follow-up assignments may be easily and quickly prepared thereby locating sources of infection and contacts and returning delinquent patients for treatment. Between July 1 and August 13, 674 blood Wassermann and Kahn tests were made under the new Saltiel law, ten of which were positive. During the same period, 709 pus smears for gonorrhea were made, three of which were positive.

KENTUCKY

Dinner to Dr. Abell—The sisters at St. Joseph's Infirmary, Louisville, gave a testimonial dinner June 17 to Dr. Irvin Abell, who has been a member of the staff for many years. Dr. Abell was recently made President-Elect of the American Medical Association.

New Psychiatric Hospital Started—Ground was broken July 31 for a new psychiatric hospital near Danville on the Shakertown Road. The state legislature recently appropriated \$2,000,000 for several projects to modernize state institutions and it is expected that further appropriations will be made and that federal funds will also be obtained. It is expected that the hospital project will eventually cost \$3,000,000. The new institution will replace the present Eastern State Hospital at Lexington; the buildings of which may be used as a diagnostic center, it is reported.

LOUISIANA

Society News—Dr. John G. Menville, New Orleans, addressed the Second District Medical Society in Destrehan, June 17, on infections of the urinary tract.—Drs. Shirley C. Lyons and Willard R. Wirth, New Orleans, addressed the Seventh District Medical Society in Opelousas, June 10, on 'Carbuncles—A New Conservative Method of Treatment' and 'Heart Disease and Pregnancy' respectively. Dr. Charles M. Horton, Franklin, president of the Louisiana State Medical Society, spoke on organization problems and activities.—The Tri-Parish Medical Society for East Carroll, West Carroll and Tensas parishes met in Tallulah, June 1, with Drs. Andros Scott, Hamilton, Monroe, and Thomas P. Sparks, Jr., Newellton, as speakers on "Orthopedic Treatment in Infantile Paralysis" and 'Formation of Kidney Stone' respectively.—Dr. James T. Nix, New Orleans, addressed the Bi-Parish Medical Society (East and West Feliciana parishes), June 2, on cancer.

MAINE

State Medical Election—Dr. Willard H. Bunker Calais, was chosen president-elect of the Maine Medical Association at the annual meeting at Belgrade Lakes, June 20-23, and Dr. Ralph W. Wakefield, Bar Harbor, was installed as president. Miss Rebekah Gardner, Portland, secretary of the association for the last four years, resigned and Dr. Frederick R. Carter, Augusta, was elected to succeed her.

MICHIGAN

Personal—Dr. John Howard Ferguson, associate professor of physiology and pharmacology, University of Alabama School of Medicine, has been appointed assistant professor of pharmacology at the University of Michigan School of Medicine, Ann Arbor.—Dr. Hugo A. Freund has been appointed a member of the Public Welfare Commission of Detroit.

Typhoid Outbreak Traced to Carrier—A temporary carrier of typhoid bacilli was discovered to be the source of an outbreak of typhoid involving fourteen cases in and near Grand

Rapids, Mich., between Dec. 9, 1936, and January 4, according to *Public Health Reports*, July 9. Investigation of nine cases in the city, four cases in adjacent territory and one in a town 21 miles away revealed that all the patients in the city and some of those in the country had eaten cream puffs bought at the same bakery. All the employees of the bakery, about 250 persons, were examined and cultures were made daily on all who were under suspicion. On the seventh day a positive culture was obtained from a person employed in filling the cream puffs with custard and whipped cream. This person was said not to have had the disease.

Care of the Mentally Ill—An integrated program of care for the insane, feeble-minded and epileptic with emphasis on prevention and a program of building expansion have been approved in legislation recently enacted according to newspaper reports. For the latter, \$3,500,000 was voted this sum to cover also an experiment in isolation of sex degenerates. A new governing body created with full power to direct this program will appoint a directing head who must have the same minimum qualifications as superintendents of the mental hospitals. Research to determine the causes and prevention of mental disease will be begun on a small scale and expanded as the new program matures. The law provides that sex degenerates regardless of whether they are legally sane, be confined at the Iowa State Hospital in special quarters until they have ceased to be a menace to society. Such persons are to be transferred from penal institutions to hospital quarters and detained after expiration of their penal sentences. Under the law, pardon or parole for a degenerate would not be possible until he had been certified by alienists as no longer dangerous. A further provision of the law offers automatically public hearings for persons who have been discharged from mental hospitals as cured to determine whether they are legally sane.

MINNESOTA

Rooms Dedicated to Physician—Two rooms and the babies' ward in the new five-story addition to St. Barnabas' Hospital, Minneapolis, were recently dedicated to the late Dr. Knut O. Hoegh for many years chief of the surgical staff of the hospital. The rooms were the gift of Maurice L. Rothschild, president of Maurice L. Rothschild and Company, Chicago, out of gratitude to Dr. Hoegh. The entire addition which increases the hospital's bed capacity to 175 cost \$275,000.

Northern Minnesota Meeting—The annual meeting of the Northern Minnesota Medical Association will be held at Virginia, August 27-28. Among the speakers on the program will be

Dr. Joseph C. Michael, Minneapolis, Insulin Shock Therapy in Dementia Praecox.
Dr. George A. Earl, St. Paul, Comparative Values of Injection and Surgical Treatment of Hernia.
Dr. Harold D. Harlowe, Virginia, Bronchoscopy as an Aid to the General Practitioner.
Dr. Jacob Arnold, Bergen, Rochester, Conditions Causing Intestinal Obstruction and Their Management.
Dr. Berton J. Branton, Willmar, Medicine, a Cooperative Business, a Noncompetitive Profession.
Hon. Niels H. Debel, St. Paul, chairman, state industrial commission, The Physician and the Workman's Compensation Law.

At the annual banquet Friday evening, August 27, the speakers will include Dr. Roscoe G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, on 'The Business Side of Medicine'. Dr. Alfred W. Adson, Rochester, president, Minnesota State Medical Association, 'The State Medical Association: A Going Concern'. James A. Merrill, LL.D., president emeritus, State Teachers College, Superior, Wis., 'The Wonderland of Lake Superior' and Dr. Oscar O. Larsen, Detroit Lakes, president of the Northern Minnesota association, who will give his official address. Dr. Frank J. Hirschboeck, Duluth, will preside at the banquet.

NEBRASKA

Society News—Drs. William L. Shearer and Warren Thompson, Omaha, addressed the Madison Six County Medical Society, Pierce, June 22, on 'The Infected Maxillary Sinus from Teeth' and 'Pulmonary Problems' respectively.—Dr. Edmund G. Zimmerer, Lincoln, assistant state epidemiologist, was the speaker at a meeting of the Eighth Council District at Rushville, recently, discussing the campaign against syphilis.—At a meeting of the Cedar, Dakota, Dixon, Thurston and Wayne Counties Medical Society, June 29, the speakers were all from Sioux City, Iowa: Drs. Howard I. Down, on 'Rectal Bleeding', Roy E. Crowder, 'Management of Breech Presentation' and Robert N. Larimer, 'Protamine Insulin'.

NEW JERSEY

State Board Election—Dr Henry B. Diverty, Woodbury, was elected president of the State Board of Medical Examiners at a meeting July 21, and R. M. Colburn, D. O. Newark, treasurer. Dr James J. McGuire, Trenton is secretary.

Physician Beaten When Answering Call—Dr Vincent G. Fay Montclair was beaten and robbed of \$40 July 21 when he answered a telephone call to attend a sick woman at 2 a. m. The Newark *News* reported Dr Fay was said to be in St. Vincent's Hospital with severe head injuries.

NEW YORK

Symposium on Silicosis—The Third Silicosis Symposium at the Trudeau School of Tuberculosis Saranac Lake was held June 21-25. Among the speakers who discussed various phases of the silicosis problem were Drs. Anthony J. Lanza, New York, Royd R. Sayers, U. S. Public Health Service, Washington, D. C., William S. McCann, Rochester, Leroy U. Gardner, Saranac Lake, Eugene P. Pendergrass, Philadelphia, Andrew R. Riddell, Toronto, Ont., Philip Drinker, Ch. E., Boston, Mr. Homer L. Sampson, Saranac Lake, Mr. D. E. Cummings, Saranac Laboratory, and Mr. T. C. Waters, Baltimore.

Personal—Dr Charles D. Shields, Buffalo, has been appointed assistant district health officer for Central New York. —Dr Simon J. Gormley, Albany has been appointed an epidemiologist-in-training with the state department of health. —Dr Raymond G. Wearne, assistant superintendent of the Central Islip State Hospital, has been appointed superintendent of the Wassaia State School for Mental Defectives. He succeeds Dr Harry C. Storrs, recently appointed superintendent of Letchworth Village, Thiells. —Dr Eugene F. McGilgan, director of Gray Oaks Hospital for the tuberculous Yonkers, has been appointed health commissioner of Yonkers to succeed the late Dr Louis V. Waldron. Dr Romeo Roberto succeeded Dr McGilgan at Gray Oaks.

Food Poisoning from Pastry Filling—About fifty persons were ill as a result of eating pastry with a cream filling purchased in the bakery section of a department store in Rochester in April. First a family of five became ill of food poisoning April 25 but the cause was not determined. The next day four members of another family became ill within three hours after eating a pie obtained from the department store. Later in the day the fifth member of this family returned home, partook of the pie and was sick within three hours. The first family on further questioning stated that for dessert a cream filled pie from the same store had been eaten. Sale of all cream filled goods was stopped at the store but no specimen of the filling sold on April 24 could be obtained. Within a few hours however reports of other illnesses came in and specimens were obtained from many households. Laboratory examination showed contamination with staphylococcus. The bakery was said to be of more than average cleanliness and the method of contamination was not determined though it was surmised that the filling may not have been thoroughly cooked.

New York City

Fellowship Awarded—The Mary Putnam Jacoby Fellowship of the Women's Medical Association of the City of New York has been awarded for 1937-1938 to Dr. Vilma Sebasta of the children's clinic at the University of Budapest for study in the United States.

Hospital Director Appointed—Dr Joe R. Clemmons, assistant director of Strong Memorial Hospital, Rochester, has been appointed director of Roosevelt Hospital, a position recently created. Dr. Clemmons is 41 years old and a graduate of the University of Tennessee College of Medicine, Memphis. The appointment is effective September 1.

Bequest for Fellowship at Columbia—A bequest estimated at \$200,000 was left to Columbia University College of Physicians and Surgeons by Mrs. Sara M. Frank, who died August 1 to found a fellowship as a memorial to herself and her husband. The income from the trust is to be used to aid any person or persons the faculty may select who show special aptitude for original work on diseases of the eye according to the New York *Times*.

Hospital News—The Rev. George F. Clover, superintendent of St. Luke's Hospital from 1900 until his recent retirement because of ill health, died July 18 at his summer home in Norfolk, Conn. Dr. Claude W. Munger, former superintendent of Grasslands Hospital, Valhalla, succeeded Mr. Clover as superintendent of St. Luke's last April. —The Brooklyn

Cancer Institute has recently obtained a gram of radium valued at \$30,000. This is the first radium the institute has received, though it was opened last October. The radium was bought by the city from Belgium.

Dr. Gonzales Appointed Medical Examiner—Dr. Thomas A. Gonzales, acting chief medical examiner since the death of Dr. Charles Norris in September 1935, has been appointed permanently to the position, having qualified in a civil service examination. Dr. Gonzales, who is 59 years old, graduated from Bellevue Hospital Medical College in 1898. He served successively as assistant pathologist, pathologist and consulting pathologist at Harlem Hospital from 1904 to 1918 when he was appointed assistant medical examiner. In 1926 he became deputy medical examiner. He is associate professor of forensic medicine at New York University College of Medicine.

NORTH CAROLINA

Faculty Additions at Duke—Dr. Joseph W. Beard, New York, has been appointed assistant professor of surgery at Duke University School of Medicine, Durham, and Dr. Walter L. Thomas, Jr., formerly of Lynchburg, Va., has been appointed assistant professor of obstetrics and gynecology. Dr. Beard graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1929 and Dr. Thomas from University of Virginia Department of Medicine, Charlottesville, in 1931.

Society News—At a joint meeting of the Cleveland Rutherford, McDowell and Polk county medical societies in Cleveland Springs, June 24, the speakers were Drs. Robert H. Crawford, Rutherford, on tumors of the mouth, Benjamin Gold, Shelby, on enuresis in children, and William M. Elliott, Forest City, foreign body in the bladder. —At a meeting of the Sixth Council District of the Medical Society of the State of North Carolina in Roxboro, June 23, the speakers included Drs. Hubert A. Royster, Raleigh, on appendicitis, Julian M. Ruffin, Durham, conditions causing bloody diarrhea, and Julian W. Ashby, Raleigh, mental diseases. —The Buncombe County Medical Society recently began publication of a four page bulletin.

Dr. MacNider Appointed Dean—Dr. William de B. MacNider, Kenan research professor of pharmacology at the University of North Carolina School of Medicine, Chapel Hill, has been appointed dean of the school to succeed Dr. Charles S. Mangum. Dr. MacNider graduated from the university medical school in 1903 and has been a member of the faculty since 1905. He has been president of the Medical Society of North Carolina and the American Society for Pharmacology and Experimental Therapeutics and chairman of the Section on Pharmacology and Therapeutics of the American Medical Association. He is a member of the National Board of Medical Examiners and associate editor of the *Journal of Pharmacology and Experimental Therapeutics*.

NORTH DAKOTA

Personal—Dr. John D. Carr has resigned as superintendent of the North Dakota State Hospital for Insane, Jamestown. —Dr. William A. Gerrish, Jamestown, has been appointed a member of the North Dakota State Board of Medical Examiners to succeed Dr. John E. Hetherington who moved from the state to Portland, Ore.

Society News—Dr. Edward M. Ransom, Minot, addressed the Northwest District Medical Society recently at Minot on "Diagnosis of Placenta Praevia." Dr. Irvine McQuarrie, Minneapolis, was a recent speaker on "Convulsive Disorders of Childhood." —A program on syphilis was presented at a recent meeting of the Cass County Medical Society in Fargo by Drs. Arthur C. Fortney, William F. Baillie, William G. Brown, Harvey J. Skarshaug and Frank I. Darrow.

OHIO

Society News—Dr. Earl H. Baxter, Columbus, addressed the Fayette County Medical Society at Washington Court House, July 8, on "The First Two Years of a Child's Life." —Dr. Andrew C. Ivy, Chicago, addressed the Lima and Allen County Academy of Medicine, Lima, June 17, on "Applied Physiology of the Liver." —Drs. Joseph S. Rardin, Alexander P. Hunt and Herbert M. Keil addressed the Hempstead Academy of Medicine, Portsmouth, July 12, on "Fractures." —The Stark County Medical Society held its annual picnic and golf tournament at the Congress Lake Country Club, Canton, June 16. At this meeting the Canton Chamber of Commerce presented to the society a gavel made of wood from the home of President McKinley, once a resident of Canton.

OKLAHOMA

Society News—The semiannual meeting of the Southeastern Oklahoma Medical Association was held in McAlester June 24 with the following speakers: Drs. William L. Shippey, Poteau, on "The More Common Cardiac Conditions: Their Early Recognition and Management"; Forrest P. Baker, Tahmina, "Tuberculosis a Family Disease"; Weldon Keiller Haynie, Durant, "Symptoms, Diagnosis and Treatment of Acute Perforated Gastric Ulcer"; Lyman C. Veazey, Ardmore, "Hypothyroidism"; and Alfred T. Baker, Durant, "Management of Diabetes Mellitus."

State Health Department in New Home—The state department of health recently moved its headquarters in Oklahoma City from the state capitol to a building formerly used as a soldiers' home. The move was made when increased appropriations and federal funds made possible enlarged activities for the health department. There are now eight bureaus and it is anticipated that the department will have about 300 employees when the program is fully launched. Twenty-one counties in the state now have full time health units under the general supervision of Dr. Charles E. Leonard. Dr. Charles M. Pearce is the health commissioner.

PENNSYLVANIA

District Meeting—The annual meeting of the Eleventh Council District of the Medical Society of the State of Pennsylvania was held at Bedford Springs July 28. Scientific papers were presented by Drs. George M. Piersol, Philadelphia, on "Rheumatic Diseases of the Heart"; Edward L. Bortz, Philadelphia, "Pneumonia Control—A Major Responsibility of the General Practitioner"; John P. Griffith, Pittsburgh, "Significance of Abdominal Pain"; and John B. McMurray, Washington, "Acute Infections of the Orbit." Dr. Maxwell J. Lick, Erie, president of the state society, spoke on "The Physician as a Molder of Public Opinion" and Dr. Chauncey L. Palmer, Pittsburgh, chairman of the committee on public health legislation, "Legislative News." Testimonials for fifty or more years of practice were presented to the following physicians:

William J. George, Johnstown	Harvey M. Griffith, Conemaugh
John A. Murray, Patton	Daniel S. Rice, Ebensburg
Henson F. Tomb, Johnstown	John M. C. Reynolds, Washington
John D. Sturgeon, Uniontown	George W. Hatfield, Mount Morris
George B. Woods, Washington	George B. Frantz, Coal Center
Colin R. Weirich, Bridgeville	

SOUTH CAROLINA

State Society President Resigns—Dr. Julius H. Taylor, Columbia, president of the South Carolina Medical Association, has resigned on account of illness. Dr. Leonidas M. Stokes, Walterboro, first vice president, has succeeded him.

UTAH

Health Districts Established—With funds from the federal government through the Social Security Act, three public health districts covering the entire state have recently been established. Dr. Welby W. Bigelow has been appointed to have charge of the northern district with headquarters in Salt Lake City; Dr. Alton A. Jenkins, the southwestern district with headquarters in Cedar City; and Dr. Edward L. Van Aelstyn, the southeastern district with headquarters in Price.

VIRGINIA

Professor Appointed—Dr. George McLean Lawson, recently professor of public health and bacteriology at the University of Louisville (Ky.), School of Medicine, has been appointed professor of preventive medicine and bacteriology at the University of Virginia Department of Medicine, Charlottesville. Dr. Lawson graduated from Yale University School of Medicine, New Haven, Conn., in 1924.

New Board for State Hospitals—Drs. Robert Finley Gayle, Jr., Richmond, and Frank C. Pratt, Fredericksburg, are physicians appointed to a new board created to have supervision over state mental hospitals. Other members of the board are Shirley Carter, Winchester; Morton Goode, Dinwiddie; King E. Harmon, Pulaski; George P. Coleman, Williamsburg; and H. Minor Davis, Lynchburg. Mr. Carter is chairman.

WASHINGTON

Public Health League Election—Dr. Harry E. Rhodeland, Spokane, was elected president of the Public Health League of Washington at the annual meeting during the convention of the Washington State Medical Association in Seattle in July. Vice presidents of the league were elected as follows: Drs. Reuben A. Benson, Bremerton; George W. Cornett, Arkuma; Roscoe W. Smith, Walla Walla; J. Bennett Blair, Vancouver; and William A. Mitchell, Colfax.

WEST VIRGINIA

Health Council Meeting—Dr. Walter E. Vest, Huntington, was elected president of the Public Health Council of West Virginia at a meeting in Fairmont in July. The council set up rules and regulations for tourist camps and trailers. The regulations call for proper drainage, adequate sanitary facilities, sewage and garbage disposal, supervision, safe water supply, and adequate refrigeration for milk and food supplies. Camps meeting all the requirements may display an "Approved" sign.

WISCONSIN

Veteran Practitioner Honored—The council of the State Medical Society of Wisconsin recently elected Dr. Benjamin J. Bill, Genoa City, an honorary member. Dr. Bill was born in 1850 and graduated from Rush Medical College, Chicago, in 1879. He settled soon after his graduation in Genoa City and has been active in the town's affairs as well as in medical fields. He was an organizer of the Walworth County Medical Society and its first president and also helped organize his district medical society and served one year as president. According to the *Wisconsin Medical Journal*, he has been a member of the state society since 1885.

GENERAL

Board Examination Postponed—The first examination in part I to be held by the American Board of Surgery, which was announced for September 20, has been postponed to October 20 according to an announcement by the secretary, Dr. J. Stewart Rodman, Philadelphia.

Changes in Status of Licensure—The Kansas Board of Medical Registration and Examination reports the following action taken at its meeting June 21:

Dr. Clarence J. McKnight, Wichita, license restored.

The board of medical examiners of Oregon recently reported the following action:

Dr. Walter M. Blowers, Portland, license revoked May 10 on a complaint of unprofessional and unlawful conduct as a physician and surgeon.

Society News—Dr. Charles E. Sears, Portland, Ore., was elected president of the Pacific Northwest Medical Association at its meeting in Great Falls, Mont., July 15-17. Because of the meeting of the American Medical Association in San Francisco in 1938, it was decided to hold only a business meeting in 1938 in San Francisco and elect officers at that time. The fifty-fourth annual meeting of the American Clinical and Climatological Association will be held in Baltimore, October 11-13, with headquarters at the Belvedere Hotel. The American Association for the Study of Neoplastic Diseases will hold its annual meeting in Washington, D. C., September 9-11.

Prevalence of Poliomyelitis—Newspapers have reported unusual prevalence of poliomyelitis in several states. Eighty-three active cases were reported from Western Kentucky towns August 6. The state health department of Oklahoma stated August 1 that 160 cases had been reported in that state during July. The outbreak in Arkansas was believed to be abating; the state health officer announced July 29 when 100 active cases were reported, twenty less than two weeks before. There have been eight deaths in Little Rock. Twenty-six cases were reported to the Illinois state department of health during the week preceding August 3. The U. S. Public Health Service reported 324 cases during the two weeks ended July 31.

Vernon Kellogg Dies—Vernon Lyman Kellogg, LL.D., secretary emeritus of the National Research Council, since 1932, died in Hartford, Conn., August 8, aged 69. Mr. Kellogg was born in Kansas and educated at the University of Kansas and later at foreign universities. He taught entomology at the University of Kansas from 1890 to 1894. In the latter year he became professor of entomology at Stanford University, California, where he remained until 1920. During and after the World War, however, he was active in relief work in Belgium, Poland, and Russia. He became the first permanent secretary of the National Research Council in 1919 and resigned in 1931 because of illness. Mr. Kellogg was honored by decorations from many foreign governments and by honorary degrees from several universities. He was author of numerous books on zoology and entomology.

Pharmacopoeia Supplement Released—The first Supplement to the U. S. Pharmacopoeia XI has been published and will become official December 1. The supplement is a book of about 100 pages and may be obtained from the Mack Printing Company, Easton, Pa., from wholesale druggists or other distributors of the Pharmacopoeia for \$1 a copy. All texts revised up to June 1 are included in the book. Each proposed change was investigated and submitted to the Committee of Revision, and the tentative text was then widely distributed to solicit criticisms and suggestions. A hearing was conducted

by members of the executive committee after which members of the executive committee held a conference with the officials of the Food and Drug Administration at Washington and decided on the text which was then submitted in full to the Committee on Revision for discussion and approval. The issuance of a supplement is to make possible prompt revision of tests and assays whenever it is found necessary and even the recognition of added therapeutically important substances if new conditions make such action desirable.

Accidental Deaths Increase—The National Safety Council recently issued its annual compilation of statistics on accidents giving data for 1936. The report shows that 111,000 persons met accidental deaths in 1936, one death every five minutes. There were 1,073,000 persons injured with permanent disability in 400,000 cases. The accident death rate was 86.4 per hundred thousand persons, an increase of 10 per cent over the previous year. Approximately half this increase was attributed to the excessive heat of 1936; the report pointed out about five times the usual average number of deaths being credited to that cause. Fatal traffic accidents increased to a new high point of 37,800 but they were exceeded by home accidents which killed 38,500. Falls killed more persons than any other accidental cause except traffic accidents. 47 per cent of the victims were women. Deaths from occupational accidents reached 18,000 in 1936 as compared with 16,500 in 1935. Fatalities in the classification "public not motor vehicle" rose 11 per cent from 18,000 in 1935 to 20,000 in 1936. Mishaps in this group covered such occurrences as drownings, poisonings and firearms accidents not covered by the other three groups and that did not involve a motor vehicle. Children from 5 to 14 years old showed the best record, a death rate of 34.6 per hundred thousand. Younger children had a rate of 76.3 and rates for other age groups were as follows: from 15 to 24, average 56.7, from 25 to 64, average 81.1 and above 65, average 398.1. A comparison of rates for men and women showed that accidents last year killed 110.2 men in every hundred thousand and only 46.1 women. The number of men killed was greater than the number who died of any disease except heart disease. Arizona had the highest accident rate for all types of accidents, 165.5 deaths per hundred thousand persons and Rhode Island the lowest, 59.3.

Medical Bills in Congress—*Changes in Status*. S 1567 has passed the Senate and has been favorably reported to the House with amendments proposing among other things that helium not needed for government use may be produced by the government and sold under regulations approved by the President, for medical, scientific and commercial use. S 1629 passed the Senate, August 14, without amendment, proposing to regulate traffic in surgical ligatures and sutures. The bill proposes that surgical ligatures and sutures, to be salable in the District of Columbia or in interstate and foreign commerce must be prepared at an establishment holding an unsuspended and unrevoked license issued by the secretary of the treasury and that the container must be plainly marked with the proper name of the article, the name, address and license number of the manufacturer and the date beyond which the contents cannot be expected beyond reasonable doubt to yield their specific results. H R 8202 has passed the House proposing to provide for the reorganization of agencies of the government and to establish the Department of Welfare. The bill provides that the secretary of welfare shall promote public health, safety and sanitation, the protection of the consumer, the cause of education, the relief of unemployment and of the hardship and suffering caused thereby, the relief of the needy and distressed, the assistance and benefits of the aged and the relief and vocational rehabilitation of the physically disabled and in general shall coordinate and promote public health, education and welfare activities. *Bills Introduced*. H R 8214 introduced by Representative Murdock, Arizona, proposes to authorize an appropriation of \$500,000 to erect additional facilities to the existing veterans facility at Tucson, Ariz., to take care of at least 200 general medical patients. H R 8225 introduced by Representative Voorhis, California, proposes to amend the Social Security Act by authorizing an annual appropriation of \$7,000,000 to be allotted to the several states to provide medical care to nonresident needy persons "on the same basis as to resident needy persons." In order to receive an allotment a state must submit plans to the surgeon general of the public health service for the medical care of nonresident needy persons. H R 8237, introduced by Representative Voorhis, California, proposes to provide for the general welfare by establishing a Cooperative Home Board and a system of Cooperative Home Associations. No person may become a member of any such association it is proposed before reaching the age of 62 and no membership may be sold for less than a minimum of

\$2,000. A membership fee will obligate the association to supply the member with housing, food, medical attention and other living necessities for the term of the membership. The United States Public Health Service is to be authorized to supply and supervise the medical service to be made available to members of such associations and to supervise the sanitary facilities of association home units, an appropriation of \$50,000 a year being authorized to enable the public health service to carry out these functions.

CANADA

Canadian Medical Election—Dr Kenneth A. Mackenzie, Halifax, N. S., was chosen president elect of the Canadian Medical Association at the annual meeting in Ottawa, June 21-25, and Dr Theodore H. Leggett, Ottawa, was installed as president. The 1938 meeting will be in Halifax.

Personal—Sir Andrew McPhail, professor of the history of medicine at McGill University Faculty of Medicine, Montreal, since 1906, will retire at the end of the present summer term, according to *Science*.—Dr Chesley F. Blackler, formerly of Montreal, has been appointed health officer of Kingston, Ont.; it is reported.

British Columbia Meeting—The annual meeting of the British Columbia Medical Association will be held in Vancouver, September 13-15, with the following speakers:

Dr Edwin E. Osgood, Portland, Ore., Therapeutic Thinking, Hypertensive Cardiovascular Renal Disease, Recent Advances in Hematology.
Dr Myron O. Henry, Minneapolis, Surgical Treatment of Intracapsular Fractures of the Hip, Fusion of Spine with Bone Chips.
Dr Burgess L. Gordon, Philadelphia, A Study of 3,000 Cases of Obesity.
Dr James D. Adamson, Winnipeg, Money and Medicine, Respiratory Sepsis.
Dr Malcolm R. MacCharles, Winnipeg, Some Problems of Biliary Surgery, Cancer of the Breast.

Drs Theodore H. Leggett, Ottawa, and Thomas C. Routledge, Toronto, president and general secretary respectively of the Canadian Medical Association, will also make addresses.

LATIN AMERICA

Society News—Dr Gonzalo Pedrosa was recently installed as president of the National Society of Surgery in Cuba. Other officers are Drs Eugenio Torroella, vice president and Vicente Banet, secretary.

Institute for Investigation of Tuberculosis—Announcement is made of the foundation of the Brazilian Institute for the Investigation of Tuberculosis in Bahia, recently. The institute plans to include in its activities all phases of the problem of tuberculosis. It proposes to establish a special library and laboratory, to sponsor congresses and lectures to provide treatment for the indigent, to publish reports of research and provide for exchange of information with other countries. Dr Jose Silveira is director of the technical and administrative work of the institute and Dr Oswaldo Gomes is secretary. Dr Edgard Rego dos Santos, director of the Faculty of Medicine of Bahia, is president of an advisory council of twenty-two members representing various fields of medicine.

FOREIGN

British Medical Election—Dr Colin D. Lindsay, honorary senior physician, Prince of Wales's Hospital and physician to the Royal Eye Infirmary, Plymouth, was chosen president of the British Medical Association for the year 1938 at the meeting in Belfast in July. Prof. Robert J. Johnstone, professor of gynecology, Queen's University, Belfast, is president for the coming year.

The Telegraph Aids Campaign Against Tuberculosis—The Swedish Government Telegraph and Telephone Board has a special blank for use on festive occasions for which it charges an extra fee of 50 ore or about 12½ cents, the additional charge going to support the fight against tuberculosis in children and the poor. The blanks are extensively used for such occasions as weddings and anniversaries and the National Swedish Society Against Tuberculosis last year received from the sale of these "telegrams de luxe" an income of almost 500,000 kronor, about \$125,000. It received more than 100,000 kronor or about \$25,000 from the sale of Christmas seals.

School for Aerial Protection in Belgium—The Ministry of the Interior in Belgium has organized a "graduate school" of aerial protection in Brussels for physicians, pharmacists, chemists and engineers according to an announcement from the Permanent Committee of the International Congress of Military Medicine and Pharmacy. The school will take account of experiences in the last war but will be constantly seeking

the most recent advances in chemistry physics physiology and therapeutics the announcement says A central library is now being organized to assemble an international documentation on the subject and it is anticipated that practical research laboratories may be established The program comprises the following features international legislation, general and special chemistry general and special pathology therapeutics procedures of identification and dosage principles of individual and collective protection, and general organization for protection

Government Services

Annual Medicomilitary Training Course

The ninth annual training course for medical department reservists of the army and navy will be held at the Mayo Foundation, Rochester Minn October 3-16 The morning hours will be devoted entirely to professional work in special clinics and study groups Officers may select the course they wish to follow from a wide variety of presentations The afternoon and evening will be devoted to a medicomilitary program under the direction of the surgeon of the seventh corps area and the surgeon of the ninth naval district This training is on an inactive duty status and is without expense to the government Enrolment is open to all army and navy reservists of the medical departments in good standing Applications should be submitted to the surgeon of the seventh corps area, Omaha, or to the surgeon of the ninth naval district Great Lakes Enrolment is limited to 200

Grants-in-Aid for Public Health Work

The Treasury Department Appropriation Act for the fiscal year ending June 30 1938 appropriated \$8,000,000 to assist states and their political subdivisions to establish and maintain adequate public health services, as authorized by the Social Security Act This sum plus balances of approximately \$1,000,000 from previous appropriations not used by the states will be allotted to the several states under regulations recently promulgated by the surgeon general of the Public Health Service These regulations provide that of the total sum available 307 per cent will be allotted to the states in the ratio which the population of each state bears to the population of the United States, 386 per cent on the basis of special health problems, such as for example, high morbidity or mortality from particular causes on a state-wide basis as malaria, hookworm, bubonic plague trachoma and typhus fever and the remainder or 307 per cent on the basis of financial need

To obtain allotments a state must present to the surgeon general of the Public Health Service a comprehensive statement showing the present state health organization programs and budget and a proposed plan for extending and improving the administrative functions of the state department of health and for extending and improving local health services Each state health officer must submit to the surgeon general for his approval, proposed budgets for carrying out each contemplated project showing the sources purposes and amounts of all funds the amounts requested from the Public Health Service for the fiscal year and such other information relating to the proposed projects as the surgeon general may require Each state health officer is furthermore required to certify that state and local expenditures will not be replaced or curtailed through the use of federal funds

Allotments to states will be available for payment when matched by state or local public funds The surgeon general however may in his discretion waive the matching requirement in those states wherein the per capita appropriation for the state department of health exclusive of funds for the maintenance of institutions exceeds the average per capita appropriation of all the states for the same purposes

Payments to the states will be made in quarterly instalments Each state health officer must submit to the surgeon general a quarterly project financial report for each budget in force and a consolidated quarterly report summarizing all budgets The reports must show the amount of public health funds actually expended and the actual expenditure of state and local funds and must contain such other information as the surgeon general may require Each state health officer must furthermore make quarterly reports of activities including (a) a report on the activities of the central administration and service projects (b) a copy of the progress report from each local health project and (c) a consolidated summary report for all projects

LONDON

(From Our Regular Correspondent)

July 24, 1937

The Annual Meeting of the British Medical Association

The 105th annual meeting of the British Medical Association was held at Belfast The president, R J Johnstone, delivered an address entitled "Some Thoughts on Medical Education," for which subject his position as professor of gynecology in Queen's University and member of the General Medical Council well fitted him He said that critics generally assumed that teachers at the end of five years should turn out a finished product, but no one expected them to turn out in the same period a finished anatomist, pathologist or surgeon Every one recognized that to form a specialist, years of graduate study and experience were necessary Was the path which the general practitioner must follow to master his art shorter and less steep than that of the specialist? He would say No The specialist must know everything about his subject, the general practitioner must know something about almost every subject Just as the finished surgeon must have responsible experience of surgery, the finished general practitioner must have responsible experience of general practice The undergraduate's horizon was limited by the threatening figures of the board of examiners Only when that grim specter had faded was he free to take a view of the responsibilities he must shoulder throughout the rest of his professional life Professor Johnstone was often asked how if practice was essential to form a good practitioner, could licensing bodies be justified in giving a license to practice to those who had no experience? He could only reply that after many years as an examiner and as an inspector of final examinations he would say that the question Is it safe to the public to allow this candidate to practice? is the dominant one in the mind of every examiner

As the practice of clinical medicine was the most important factor in forming the young practitioner and was to be his chief pursuit, would be reformers of the curriculum demanded still more clinical study in the education of the undergraduate He would be the last to disagree, but one should not be led into the fallacy of thinking that clinical training was the end all of medical education The nurse in her training had better and more prolonged opportunities for clinical observation than the medical student But did this enable her to take on the function of a medical practitioner? She would be the first to say No She lacked the background of anatomy, physiology and pathology which the medical student had gained with much toil and sweat and against which his clinical observations were composed and the picture interpreted It was the main business of medical education to provide an adequate background and to teach how it should be used

GRADUATE TRAINING

Professor Johnstone thought that most graduate courses tried to administer too much in too short a time There were possibilities of graduate training in linking up practitioners with hospitals, as Sir Farquhar Buzzard suggested last year, but there were many administrative problems to be overcome Perhaps in the future all difficulties would be solved by the establishment of a state medical service, but like good democrats we should always oppose it Every fresh instalment of social and public health legislation brought us nearer to the totalitarian ideal When that had arrived we might say goodbye to the general practitioner as we know him

THE GENERAL PRACTITIONER

How did the general practitioner compare with his predecessor of a generation back? His equipment was undoubtedly better He had for the service of his patients a store of knowl-

edge and an acquaintance with technical resources not dreamed of when Professor Johnstone was a student. Attendance in the wards and in the outpatient rooms, still more residence in hospital, long a feature in Irish medical schools and soon to be introduced in the United Kingdom generally, was an education in behavior no less than in clinical medicine.

THE HEMORRHAGIC STATES

At a joint meeting of the sections of medicine, pathology, bacteriology and immunology, Prof. L. J. Witts opened the discussion on the hemorrhagic states. He was increasingly impressed by the frequency and diversity of hereditary hemorrhagic diseases and their resistance to treatment. The study of hereditary diseases in man had been vitiated by premature dogmatism and expectation of a constancy in inheritance which the student of genetics in plants and animals would from the first have thought improbable. Hereditary hemorrhagic diseases in man were not subject to immutable laws in pattern and pedigree. It was wiser to think in terms of affected family groups than of specific diseases and laws of heredity. The local application of coagulant snake venom was the only new treatment of which the value had been confirmed. The venom of Russell's viper (1:10,000 solution) or of the Australian tiger snake (1:5,000 solution) had been chiefly used (Macfarlane and Barnett, 1934; Rosenfeld and Lenke, 1935). Loose clot was washed away from the bleeding point and tampons soaked in the venom solution were applied. With the use of snake venom in hemophilia it was now possible to repair wounds or to carry out small operations, such as dental extraction, which would previously have been fatal.

SULFANILAMIDE IN PUERPERAL HEMOLYTIC STREPTOCOCCUS INFECTIONS

In the section of obstetrics and gynecology, Dr. G. F. Gibberd said that the new aniline derivatives had been employed at Queen Charlotte's Hospital since 1936. In the doses in which they had been given their use appeared to be free from serious danger and had been followed by a great reduction in the mortality of hemolytic streptococcus infections. Analysis of the causes of this improvement showed that it was associated mainly with a decrease in the widespread invasion of the tissues by the hemolytic streptococcus rather than with a greater tendency to resolution of the disease once widespread invasion had occurred. This feature made it necessary to consider whether the improvement was due to the treatment or to a change in the virulence of the streptococcus. It was possible that both factors might be concerned. In nonfatal cases in which the tissues beyond the limits of the birth canal had been invaded by the streptococcus there was some evidence that the new drugs did hasten resolution of the inflammatory process, and this was a good reason for believing that the treatment, rather than a change in the virulence of the streptococcus, was responsible for the improvement.

While he was unwilling to guess how far the new drugs had been responsible for the undoubted improvement, he said that there was every reason to continue to use them until their value had been definitely determined.

THE FLOGGING OF CHILDREN

At the meeting of the Representative Body, an unusual subject was brought forward. A member moved that the judicial flogging of juvenile delinquents was highly undesirable, harmful in its effects and useless as a deterrent from crime and should no longer be statutory. Psychologists were unanimous in condemning it. A board of education inquiry had shown that over 80 per cent of juveniles so treated were recharged within a short time. Finland, Sweden and Norway were the only European countries which allowed judicial flogging. In the debate, opinion was divided. It was said that some children

were of such a character that flogging was the only means of dealing with them and that it was a deterrent not only to them but to others. It was pointed out that a special committee appointed by the government was considering the question and a motion to pass to the next business was carried.

NUTRITIONAL NEEDS IN PREGNANCY

At a joint meeting of the sections of obstetrics and gynecology and the new section of nutrition, Sir Robert McCarrison said that all the essential foodstuffs required in pregnancy were provided by the following in order of precedence: 1. Milk and its products. 2. Whole or lightly milled cereal grains, in particular, a good whole meal bread or standard bread, and oatmeal. 3. Green and leafy vegetables. 4. Root vegetables, particularly potatoes, carrots and onions. 5. Fruit, including the tomato. 6. Pulses. 7. Egg. 8. Meat, including fish, fowl and glandular organs. To these there must be added in this country cod liver oil, not in the large doses commonly prescribed but in the sufficient dose of a teaspoonful daily. As an additional assurance of functional efficiency of blood, muscle and nerve yeast extract was a wise precaution.

Dame Louise McIlroy, gynecologist, said that it was an easy way out of the difficulty for the physician to prescribe gallons of cod liver oil and tablets of mineral salts but that it was an artificial procedure. Fresh herrings, which contained vitamins, were often unobtainable because of the difficulty of transport. What was the diet of the average working class mother today? One had only to look at the shops. Windows were heaped with bread made from milled flour and cans of every conceivable food, meat, vegetables and fruits. These canned foods were appetizing and ready prepared but in spite of assurances to the contrary could never replace fresh foods. How many antepartum clinics concerned themselves with lessons in the preparation of food? It was all very well for laboratory workers to publish lengthy treatises on food values. The whole communal system broke down in the hands of the woman of the house, whose lack of knowledge of cooking and storage was responsible for the destruction of the main vitamin content of the food with which she supplied herself and her family.

PARIS

(From Our Regular Correspondent)

July 24, 1937

The Antinoise Campaign in Paris

Some time ago, a committee was appointed by the Académie de médecine to study means to suppress noise, which has been especially noticeable since the use of the radio has become more widespread in the residence sections. Some progress had been made in a similar campaign a few years ago through prohibiting the use of automobile sirens between the hours of 9 p. m. and 7 a. m.

The committee, headed by Dr. Pouchet, made the following report at the June 22 meeting:

1. The order of the police department, previously issued as to the interdiction of the use of automobile horns, should be changed to include the hours between 10 p. m. and 7 a. m.

2. The noise from all automobile and motorcycle exhausts should be suppressed. A previous (1931) rule has not been strictly enforced, the worst offenders being motorcycle riders and drivers of pleasure cars.

3. Between the hours of 10 p. m. and 10 a. m. the use of all loud radios is prohibited. This will be welcome news if enforced, to all citizens living on narrow streets or in apartments in which sound travels across floors, partitions or inner courts.

4. All chauffeurs should be requested to slow up at street crossings.

The French Gynecologic Congress

The sixth French Gynecologic Congress was held at Toulouse, May 15-18, under the presidency of Professor Meriel of Toulouse, and the subject for special reports and discussion was cancer of the uterus.

The first paper was by Drs Hamant and Chalmot on the diagnosis of cancer of the cervix. Every irregular hemorrhage calls for a vaginal examination. This applies particularly to intermenstrual bleeding of women who have not reached the menopause, the atypical hemorrhages during the latter period and all serosanguinolent discharges. The difficult cases to diagnose are those in which the cervix is hidden behind a fold of vaginal mucous membrane or an atresia. Palpation and use of the ordinary speculum yield little information. It is advisable to dilate or even incise a stenosing fold under anesthesia in order to exclude a cancer by biopsy from a senile metritis in which the cervix lies bathed in pus. The Lahm-Schiller test is of only relative value and is incomplete without a biopsy. Hysteroscopy as a rule is used only for cancers of the body of the uterus, but it may be helpful in certain endocervical cancers. A method termed hysteromucography has been but little employed up to the present. After injection of an opaque medium (colloidal suspension of thorium) into the cervical canal, an x-ray examination is made. The oxide of thorium is seen to be deposited on the surface of the endometrium. Biopsy, in cases of cervical cancer, is not always decisive, many contradictory results having been noted. A positive result can be regarded as confirmatory but a negative one does not exclude the presence of a cancer.

The second paper, on operative treatment of lymph node involvement in cancer of the cervix, was read by Dr Dieulafe. Although the lymph nodes are malignant in only one third of the cases, they should not be considered as negligible factors. Some surgeons advise removing the lymph nodes in every case with the adjacent cellular tissue. Faure of Paris removes only those which are to be felt and seen in the pelvic tissues round the uterus.

The third paper was on cancer of the cervix following subtotal hysterectomy for nonmalignant conditions. Lefebvre and Gouzi, who presented this paper, did not believe that total hysterectomy is indicated in every case of uterine fibroids. The increased risks over the subtotal operation are not compensated by the incidence of the postoperative development of cancer in the cervical stump.

The fourth paper was on recurrences and metastases in cervical cancer, by Dieulafe and Curtillet. The majority of recurrences are observed during the first five years after treatment. The fact that recurrence takes place does not mean a high degree of malignancy in the original tumor but rather inadequate primary treatment. In general, the prognosis has been unfavorable up to the present but the results with teleoroentgen therapy appear promising. Even though complete cure cannot always be expected in recurrent cases, at least life can be prolonged by early diagnosis and energetic treatment.

A paper on the biologic diagnosis of cervical cancer was presented by Prof Max Aron of Strasbourg, whose technique is based on the theory that toxins can be eliminated by the kidney in cancer cases, either from degenerated cells or from other as yet undetermined causes. The urinary extract is employed as an antigen in the presence of the patient's serum, resulting in a flocculation reaction. In 155 serums from cancer cases there were 124 (80 per cent) positive, twenty-two (14 per cent) doubtful and nine (6 per cent) negative results. In 222 noncancer cases used as a control there were six (3 per cent) positive, nine (4 per cent) doubtful and 207 (93 per cent) negative results.

Dr Michon of Lyons spoke on surgical treatment (except during pregnancy). At present only cases in groups 1 and 2

of the Geneva classification are considered operable. In these, the cancer is limited to the cervix without demonstrable parametrial involvement. The mortality varies from 266 to 9 per cent and the end results show 40 per cent of cures.

Influence of BCG Vaccination of Children on Tuberculin Tests

In a paper read at the June 1 meeting of the Académie de médecine the results of the vaccination and revaccination (with the BCG vaccine) of 156 children were reported by Foley and Parrot of the Pasteur Institute of Algiers, in the French colony in northern Africa. The children varied in age from new-born to 15 years, the vaccine being given by mouth or subcutaneously. All those who were vaccinated lived in a community close to the Sahara desert in which tuberculosis is rare, hence the interpretation of the effects of the vaccination on the sensibility of those who have been vaccinated to tuberculin does not risk being influenced by intercurrent tuberculous contamination. Certain of these children had received a single vaccination or a revaccination (subcutaneous) and from three to five buccal vaccinations over a period of from three to six years. The amount given at each vaccination was from 5 to 30 cc of the BCG vaccine, each child receiving up to 0.08 mg subcutaneously and 0.65 Gm by mouth. At least twice a year, during a period of eight years, epidermal and intradermal tuberculin control tests were made.

Of 156 children thus vaccinated and revaccinated several times, either by the subcutaneous or the buccal route, thirty-nine have never had positive epidermal reactions. Among these thirty-nine children, thirty-one have had a positive intradermal reaction. With the use of from 0.1 mg to 0.01 Gm, the proportion of allergic children rose from 117 of 156, or 75 per cent to 148 of 156, or 94.8 per cent. The inadequacy of the epidermal reaction becomes still more apparent when a group of twenty-five children who had been given only a single buccal vaccination is analyzed. There were only 8 per cent positive epidermal as compared to 88 per cent positive intradermal reactions.

The same defects of the epidermal test are evident if it is compared with the intradermal test when a search is made for allergy in nonvaccinated children. In another community, in which tuberculosis is also rare, fifty-nine children were given simultaneously the epidermal and dermal tuberculin tests. The epidermal reaction was positive in all, but the intradermal reaction in only eight of thirty-two with 0.01 Gm and in only four of twenty-seven with 0.02 Gm, a total of twelve or 20.3 per cent of the fifty-nine showing an intradermal reaction. Hence, if only the epidermal test had been employed, the conclusion would have been reached that no tuberculosis existed, whereas in reality as shown by the intradermal reaction there were 20.3 per cent positive. The latter observation appears to render doubtful the value of the two preliminary epidermal tests usually employed to determine the necessity of antituberculosis vaccination of older children.

The authors stated that one is not justified in affirming the absence of prevaccinal or postvaccinal allergy on the basis of negative tuberculin skin reactions, even though repeated, or on the other hand in giving more tuberculosis revaccinations until the epidermal reaction becomes positive. The authors agree with Debre and his co-workers that a number of vaccinated children who have a negative epidermal reaction are in reality allergic. This is shown by the results of the intradermal reaction when sufficiently large doses are used. The same is true for nonvaccinated children. Before concluding that a vaccinated or nonvaccinated child is not allergic, one must employ also the intradermal reaction, with increasing doses of tuberculin up to 0.01 or 0.02 Gm in one of the doses. When two preliminary epidermal tests have been used in order to determine the proper moment for vaccinating older children, one runs the risk of a

false security and an erroneous interpretation of the results of the BCG method of vaccination. The preventive value of the latter can be strictly judged only by prolonged observation of vaccinated children from birth, and after revaccination at regular intervals.

How to Prevent Tularemia from Becoming Endemic

The recent appearance of tularemia in Turkey (Macedonia), Austria and Czechoslovakia renders it important to guard against its introduction into France, as many alive and dead pheasants, partridges and rabbits are imported from those countries in which the disease is prevalent. At the June 22 meeting of the Académie de médecine Dr. Emile Brumpt called attention to the danger. It seems hardly probable that the disease should have been introduced into heretofore immune European centers by emigrants from infected countries, because the interhuman mode of contagion is denied by all investigators. It is possible, however, that these emigrants should have imported tularemia with their ectoparasites or their cattle. Other sources of contagion are, first, the wool or skins of animals, in which the pathogenic bacteria can remain alive for from thirty to forty-five days, and, second, dead animals imported for food purposes. It does not seem likely that migratory birds act as carriers. The one certain fact is that tularemia can be brought into France by various means of transportation. Following the reading of this paper, a committee was appointed to study the question.

New Legislation on Induced Abortion

The *Oesterreichisches Gesetzblatt* recently published the text of a new statute which has supplanted all previous abortion legislation and the official title of which is 'Statute for the Protection of Germinating Life.' It was the subject of considerable debate in the Bundestag prior to its passage by that body. The Bundestag has taken the place of the former "Parliament" and is the sole channel through which the representatives of the people can express themselves with respect to the proposals of government. The new legislation is based on the old, but its punitive provisions are more rigorous and there is a new feature, the creation of so-called boards of medical verification. Henceforward any physician who is convinced that the life of a pregnant patient is endangered by her condition and can be saved only by induced abortion must submit the facts to one of the new boards. There is one such board to each administrative district. Each board is in fact a committee of three members, including the chief health officer of the district and two specialists, one of whom must be either a gynecologist or a surgeon and the other an internist. If necessary this "collegium" can call on other specialists for expert testimony. It is the duty of the board to ascertain by examination of the case record 'whether all possible means of preserving the germinating life have been exhausted.' The final decision is, however, left to the conscience and sense of responsibility of the physician. The gravid woman is under no obligation to appear before the board for medical examination. The board's recommendations are of two kinds, temporary and final. Under the designation "temporary" would belong a recommendation that the patient be placed under observation in a hospital or recommendations of other hygienic and medical measures designed to avert the danger to life. A "final" opinion might be that the case was not one in which the continuation of pregnancy would entail the certain death of the mother or, conversely, that all possible medical measures for saving both mother and child had been exhausted. The local verification board gives the physician no "orders," nor does it issue any "official instructions," rather it simply functions as a fact

finding body. To the board's report is appended a protocol containing the opinions of individual members. If the patient has not appeared for examination, this fact too is recorded in the protocol. The law expressly forbids that induced miscarriages take place elsewhere than in a hospital unless the patient is in too serious a condition to be moved. In a case of induced abortion or miscarriage, the verification board must be notified within twenty-four hours. If more than one violation of the new law occurs within a private nursing home the place may be closed by the police. The verification boards are in general to be maintained by public funds, but a patient's means can be assessed the costs of the board's activity in his particular case.

These reforms are to be supplemented by other legislation which will be designed to facilitate marriages of members of the "celibate" occupations who were formerly forbidden to marry. New legislation is also contemplated which will grant certain tax exemptions and so on to families having more than two children. This stringent "Statute for Protection of Germinating Life" went into effect just one week after its promulgation, although it is customary for an interval of three months to elapse between the public announcement of new legislation and the date on which it becomes law.

Vienna's World War Memorial to Physicians

A beautiful memorial to the Austrian physicians who fell in the World War has been unveiled in the garden of the General Hospital. Participating in the ceremony were the president of the republic, the members of government and representatives of every medical organization in Austria. The cenotaph consists of a single sarcophagus like block of the finest marble 10 feet long by 3½ feet wide. A relief on the front side represents a scene from the World War. An army surgeon falls victim to an enemy bullet just as he is rendering first aid to a wounded man. It should be mentioned in this connection that, during the war years 1914-1918, 296 physicians of the old monarchy were victims of the conflict and eighty-seven of these men were from the region contained within the frontiers of present day Austria. The dedicatory inscription reads "The Medical Profession of Austria, to Its War Dead."

Growth of Vienna's Hospital Activities

Prof. A. Baumgarten, director of the Vienna Municipal Hospital, submitted to the Vienna Chamber of Physicians a report on the expansion of the city's hospital activities. From 1924 to 1935 the number of patients admitted to public hospitals increased by 20,000, the number admitted to private hospitals by 22,000 and the number of days in hospital by more than 100,000. All these increases took place in spite of the fact that a decrease had been anticipated. This expectation was based on numerous observations: the population of Vienna had declined by some 300,000, a large number of new hospitals were being built in those provincial towns which had been accustomed to send their sick to Vienna for hospitalization, and the influx of foreign patients into Vienna was arbitrarily stopped by political and economic circumstances. Further factors that seemed to augur a decrease in the number of hospital patients were the tremendous drop in the birth rate during the years in question, the marked diminution in the number of tuberculosis patients, the foundation of new homes for the aged, and the feeling prevalent among the working class that one should be absent as little as possible in order not to imperil one's job.

The actual increase in the number of patients is not to be explained by the expansion of medical activities or by a greater need for hospitalization among the population as a whole. But as Dr. Alfred Bass, former head of the municipal health insurance, explained, the enormous increase in the number of sick days in private hospitals during the years in question

resulted from the erstwhile foundation of two new sick insurance organizations, one for federal employees, the other for municipal employees of greater Vienna. These two insurance units also handle family insurance, permit the patient a free choice of both surgeon and internist, and indemnify the patient for his stay in the hospital. Under these circumstances many sick persons will decide more quickly for an operation. This accounts for the great increase in the number of applications for hospital beds and the rise in the actual number of beds. There were available 9,082 beds in 1913, 12,969 by 1924 and 13,902 in 1935. Although the number of private hospital beds increased by 1,100 between 1924 and 1935 the number of public hospital beds declined by around 162. The average proportion of beds in use in the public hospitals remained a constant 88 per cent, the corresponding figure for the private hospitals declined, however, from 97 per cent in 1924 to 83 per cent in 1935.

Campaign Against Acute Anterior Poliomyelitis

The advent of summer finds the health authorities prepared for a relentless campaign against acute anterior poliomyelitis. The president of the National Bureau of Health has issued a circular letter of instructions to local health officers throughout Germany. The number of cases of acute anterior poliomyelitis amounted in 1936 to 2,256, whereas in 1935 there were 2,080 cases and in 1934 only 1,701. The infection seems to become more prevalent in July, to continue in a precipitous rise till the end of September, and sink again to a lower level only in the last quarter of the year. It therefore becomes urgently necessary that abundant supplies of poliomyelitis-convalescent serum should be readily available in all parts of the country. A national supply of about 80 liters of convalescents' blood should be on hand for the treatment of 2,000 cases. The abstraction of the blood, formerly completely restricted to the hospitals is now, in the interest of saving time and money, permitted in suitable cases to be performed by the proper health officers and accredited physicians outside the hospital. The blood must be forwarded at once to the Behring Werke (a pharmaceutical house that handles serum) in special receptacles provided by that firm. Each donor will receive a so called recognitory fee of one mark for each 10 cc of blood supplied. To prevent the cost of serum from rising too high no other remuneration is permitted. For improving and expediting the serum depot service an official census of former convalescents is to go forward in the various administrative districts. By "convalescents" is meant in this instance all persons more than 6 years of age who, within the last five years, have had certain acute anterior poliomyelitis and who are now in good health. Suitable persons from this group will be asked to serve as donors and in emergencies abstractions of blood may be made compulsory. Negotiations with respect to child donors will be carried on through the parents. The larger hospitals also will cooperate with this program. Finally, the newspapers will carry suitable information with regard to the disease and to the organized distribution of serum.

Action of Vitamin C in Diphtheria

Prof. Dr. K. Kumagai of Osaka, the Japanese clinician, reports in the *Klinische Wochenschrift* on his studies of vitamin C therapy in necrotic diphtheria. The hospital of which he is director admits more than 2,000 diphtheria patients each year; the mortality fluctuates between 13 and 17 per cent. The death rate for necrotic diphtheria is higher. For several years an effort has been made to discover a therapy that would be even more effective than vigorous serotherapeutic measures (administration of from 20,000 to 50,000 units), intravenous

injections of dextrose and injections of epinephrine. Experimental injections of vitamin C have been given since 1936. According to the author, these experiments have met so great a measure of success that they deserve to be regarded as epoch making for the treatment of necrotic diphtheria. From 400 to 600 mg of vitamin C is administered daily. The effects of the medication are speedily manifested: first the fetor characteristic of necrotic diphtheria disappears, then in a few days the appetite returns and the patient feels stronger. A greater amount of urine is voided, albuminuria subsides and the pulse becomes regular. From 50 to 70 per cent of necrotic diphtheria cases formerly ended fatally, but after introduction of the vitamin C therapy the mortality fell to 30 per cent. Supplementary administration of epinephrine is recommended, as it improves the chances of favorable outcome. The earlier the injection is given the more pronounced will be its effect. Injections of serum in small doses will be of maximal therapeutic value if combined with an administration of vitamin C.

Cancer Research

Professor Borst, ordinarius of pathologic anatomy at Munich University, recently lectured before the Berlin Medical Society on the status of cancer research. Animal experimentation continues to be the most important sphere of cancer research activity. The readily practicable homoplastic transplantations of tumor tissue are still of greater experimental significance than grafts of the heteroplastic type. For the latter it is necessary that each implant should be heterogenous, and its behavior within the organism of the host is therefore not to be compared with that of autogenous neoplasms. The results of experimentation with so called irritation cancers, namely, those produced by mechanical or chemical action, must be applied to human cancer only with the greatest reservation.

Carrel's discovery of tissue culture raises high hopes that a solution of the cancer riddle will be found; yet to date Carrel's observations of the direct transition of healthy cells into cancer cells within the culture have not received general verification. The problem of neoplasms is a problem of growth, and that fact cannot be overemphasized. The search for the growth substances is rooted in a knowledge of this axiom. Here too investigation has yielded little; the observations are contradictory and do not bear comparison, in fact they tend rather to confuse than to clarify. The same substance, for example, may act toward cancer in both a pathogenic and an inhibitory way, according to how it is applied. With respect to the interrelation of sex hormone and the pathogenesis of tumors, one fact at least has been established: it is possible by protracted administration to rabbits of estrogen to produce neoplasms which appear quite similar to cancers and which perhaps may be malignant. But thus far it has been impossible in experiments of this type to observe a single instance of carcinomatous metastasis. Lately there has been widespread search for "the cancerogenic substance." This aspect of cancer research was inaugurated by the experimental paintings with tar products (paraffin, tar, dyestuffs) and with the products of metabolic decomposition (indole, skatole and so on). True carcinomas could be produced by scarlet red and sudan. The Japanese scientists have been able to produce cancer of the liver, stomach and urinary bladder as well as sarcomas by means of azo compounds and diazo compounds. They have even been able to demonstrate that the seat of the cancer differed according to the chemical constitution of the cancerogenic substance. English research workers were able to isolate genuine cancerogenic agents such as benzopyrene and dibenzanthracene from the cholesterol series. Numerous other influences—tobacco, various types of rays and so on—can produce cancer. Therefore it may well be asked whether a general factor in cancer is not some form of chronic inflammation, proof of such a hypothesis, however, is not forthcoming.

With regard to a predisposition to cancer it has now been proved that a hereditary predisposition exists, however, the acquired predispositions and the exogenic factors have a larger part in the ordinary human cancer than does heredity. According to a new theory of the pathogenesis of cancer, a cellular mutation from the healthy to the cancerous seems to be effected by exogenic stimuli. This theory may explain much but it can scarcely be regarded as a solution of the cancer problem.

The difficulties that beset an early microscopic diagnosis of cancer are not inconsiderable. The statistical records of the Munich hospital for the past thirty years show that incorrect diagnoses were made of 33 per cent of cancer cases in which the seat of malignancy was the internal organs. No reliable method of early serologic diagnosis has been evolved. Later diagnosis on this basis often depends in part on whether or not the blood and the tissue have undergone primary alterations. The collection of data on cancer, especially international statistics, is fraught with great difficulty. The regional distribution of various forms of cancer complicates the statistical picture. Thus, for example, an exceedingly large number of pulmonary cancer cases are reported from Dresden, whereas Cologne reports a disproportionate incidence of esophageal carcinoma. On the basis of the huge mass of necropsy statistics collected by the National Anticancer Committee of Germany among 22,000 cases of cancer in males more than 20 years of age, 58 per cent were cases of gastric carcinoma.

Stores of Serum for Emergencies

In order that serums, which cannot be kept for any length of time in ordinary pharmacies, may be readily available for emergency use (at night or on Sundays, for example) the larger hospitals of Berlin have set up "emergency stores of serum." The following types of serums are to be kept on hand: anaerobic, botulism, antibacillary, antidiphtheric, gas gangrene, antimeningococcus, antianthrax, peritonitis, erysipelas, antiscarlatinal, antistreptococcus and antitetanic. The serum supplies will be maintained in connection with the hospital dispensaries; serum can be requisitioned only on the order of a physician. The stores of serum are under surveillance at all times and the serums are constantly inspected against any loss of potency due to aging.

Reform in the Medical Inspection of Schools

Dr Ledent has just published some data on the present state of medical inspection service in the Belgian schools and on the need of reforms. At present from 40 to 60 per cent of children of elementary school age require medical attention. This presages that in the future 40 per cent of young men will be not fully qualified for military service. Eight per cent of children in the elementary group are three years behind their classes. There are 5 per cent of elementary school children who require special instruction. There is no medical inspection in the kindergarten classes, nor is it generally a part of secondary school routine at the difficult period of puberty, although it has quite recently been established in trade schools. The service at present entails a disbursement of about ten million francs, and the results are far from satisfactory. Flaws are to be observed in every aspect of the service: biopsychologic deficiencies of the children, faulty central administration, faults attributable to the communal councils, deficient collaboration of the teaching personnel, indifferent attitude on the part of parents, lack of altruistic attitude on the part of physicians. Accordingly, a "complete reorganization of medical inspection service in the schools," as every one calls it, has become the favorite object of study of various bodies, among them the Ministry of Education, the Parliament, the Conseil superieur

d'Hygiene and the Conseil superieur d'Education physique et de Sport, the Federation Medicale Belge, and numerous other scientific and pedagogic organizations in convention and out of convention.

From all this deliberation, no tangible program has resulted. The true objectives of a reorganization were set forth at the Congress of School Hygiene which met at Brussels in 1935: (1) surveillance of the sanitary conditions of every school, (2) cautioning of the school population against the menace of contagious diseases, (3) collection of data on the capabilities of the pupils, their growth and physical and mental aptitudes, and (4) instruction of both teachers and pupils in the rudiments of hygiene. Proposals for amelioration of the present situation may be summarized thus: 1 Legislation that would make compulsory a standardized medical inspection in all schools and whereby the central authorities would be empowered to inflict penalties for any omissions or negligence in this regard. This generally approved measure awaits only parliamentary sanction. 2 Appointment of active medical practitioners to school inspection service. This proposal has been so hotly opposed by the medical profession in general and by the Federation Medicale Belge that the ministry seems to have abandoned hope of its enactment. 3 Separate services to deal with the disparate needs of the urban as against the rural areas. It is proposed that in large cities and industrial towns the physicians on school medical service should devote about one half of each working day to this service, meanwhile retaining their general or specialized practices. Such an arrangement has already been adopted by many communities. In the villages the local physician will be assigned to inspection of a school or group of schools. He will receive instructions from a medical officer especially appointed by the Ministry of Inspection to supervise this rural service, namely, surveillance of both public community schools and private schools, approved or susceptible of being approved.

Tuberculosis Among Coal Miners

Messrs Courtois and Leclerc submitted to the Belgian Tuberculosis Society a report on "The Incidence of Tuberculosis Among Belgian Coal Miners." In industries that entail the inhalation of silicious dusts, a certain number of workers present an anatomic-clinical syndrome that goes by the name of "silicosis." Tuberculosis exacts a heavy toll among workers so affected. Certain groups of coal miners present this silicotic syndrome and among these tuberculosis is equally common. It is observed that differences in the incidence of both silicosis and tuberculosis exist between one mining region and another, and even between groups of workers within the same region. An investigation sponsored by various industrial insurance organizations of Belgium (federations de mutualites) elicited the fact that tuberculosis is equally frequent among the coal miners and other workers within the Liege area, although it is much more frequent among the former than among other workers in the districts of Charleroi and Bornage. In the Charleroi area, despite the fact that tuberculosis is rare among the coal miners who do not present the silicotic syndrome it is on the other hand frequent among those who are already suffering from this syndrome. Workers in industries that create silicious dust, although they are frequently tuberculous, tend to manifest the disease at a relatively advanced age. Tuberculous coal miners are, accordingly, regarded as "old" patients. Despite the fact that in other occupations the maximal incidence of tuberculosis lies between the ages of 25 and 30, among coal miners it lies between the ages of 40 and 45. Seldom is tuberculosis contracted by a coal miner before 30 years of age, a time of life at which among other workers the disease makes its greatest ravages. The inhalation of certain dusts (coal dust and limestone dust for example but not silica it would seem) protects the lungs for a considerable time against

the genesis of a tuberculous process. The physiopathology of the reticulo endothelial system provides a plausible explanation of this phenomenon. This report offers further proof of the similarity existing between silicosis as it affects Belgian coal miners and silicosis as described by Anglo-Saxon and German writers. Whether silicosis is a distinct entity or whether it merely represents a syndrome of tuberculous infection, it is obvious that an "occupational" and more precisely a "dust" factor underlie its manifestation and frequency among certain groups of workers.

Brussels Physicians Protest a Judicial Confiscation

An examining magistrate requested certain information of the professor who is head physician of one of the university clinics. The doctor refused the request on the grounds that to furnish the desired information would constitute a violation of the principle of professional secrecy. The judge then caused the case records of the clinic to be forcibly impounded and removed therefrom the history of a patient who had become the subject of a judicial investigation. The Brussels College of Physicians has appealed to the minister of justice for protection from a repetition of such violation of the principles of medical professional secrecy, since the maintenance of these principles is of great social and humanitarian importance. The observations jotted down by doctors to assist them in diagnoses are to be classed as professional secret records, the inviolability of which is nominally upheld by law.

Marriages

HOWARD THOMPSON HOLDEN, Chattanooga, Tenn, to Miss Dorothy Rodes of 'Rose Hill' near Crozet, Va, in June

CHARLES HAMPTON MAUZY JR, Harrisonburg, Va, to Miss Elizabeth Anne Thaxton of Tye River, June 19

C MILTON MEELS, Manhasset, L I New York, to Miss Heloise Sutherland of Westville, N S, July 24

FREDECK RALPH PERSON, Williamsburg, Va, to Miss Dorothy Italea Speese of Roanoke, June 12

WILLIAM O WHETSELL Bowman, S C, to Miss Margaret Elizabeth Daniel of Columbia, in June

JOSEPH WILLIAM WELLS New Orleans, to Miss Sara Alice Simmons of Memphis, Tenn, June 6

ELMER SHERMAN ALLEN JR, Arcola, Ill, to Miss Jane Chloe Jarman of Oklahoma City, June 30

JAMES EUGENE HEMPHILL, Petersburg, Va, to Miss Mary Nancy Ray of Richmond, June 21

CLAYTON ALTON ADAMS JR, Trenton, Fla, to Miss Marie Lang of Brunswick Ga, May 30

ARCHIE LIPE BARRINGER to Miss Mary Evans Foil, both of Mount Pleasant, N C, July 14

WILLIAM MCKENZIE BICKERS to Miss Virginia Fitzpatrick, both of Richmond, Va, June 5

HERBERT BLAKE, Anderson S C, to Miss Mary Clarence Bramlette of Laurens in June

CHIVOUS YULAN WASHBURN, Shelby, N C, to Miss Lillian Logan of Baltimore, May 25

LOUIS E AUDET to Miss Anna Rhodes, both of Williamsport, Pa, June 20

Deaths

James Ramsay Hunt @ New York University of Pennsylvania Department of Medicine, Philadelphia, 1893, since 1931 professor of neurology at Columbia University College of Physicians and Surgeons and formerly professor of clinical neurology, clinical professor of nervous diseases and associate professor of nervous diseases, director of the neuropsychiatric division of the New York Neurological Institute, consulting neurologist to the Psychiatric Institute, the Babies' Hospital, New York Ear and Ear Infirmary and Lenox Hill Hospital, New York, and the Letchworth Village, Thell's, formerly consulting psychiatrist to Lying-In Hospital New York Hospital and Randall's Island institutions, consulting neuropathologist to the Craig Colony Sonyea member of the Association of American Physicians, American Society for Clinical Investigation and the American Psychiatric Association, member and past president of the American Neurological Association, New York Neurological Society, American Psychopathological Society and the Association for Research in Nervous and Mental Diseases, corresponding member of the Societe de neurologie de Paris, served during the World War, aged 65, died, July 22, at Katonah, N Y

Samuel Andrew Woodward @ Fort Worth, Texas, Memphis (Tenn) Hospital Medical College 1894 fellow of the American College of Surgeons, past president of the Tarrant County Medical Society, member of the state board of health, formerly member of the state board of medical examiners, served during the World War, formerly dean and professor of clinical gynecology, Medical Department of the Texas Christian University, Fort Worth, member of the staff of the Harris Clinic-Hospital, visiting surgeon and gynecologist to St Joseph's Infirmary, All Saints and Baptist hospitals, district surgeon to the Frisco and Missouri Pacific railways, Texas Lines, aged 64 died, May 6, in a local hospital, of pulmonary infarction, following a fracture of the right femur received in a fall

Arthur Laphorn Smith, Virginia Water, Surrey England, Laval University Faculty of Medicine, Quebec, Que 1876, M R C S, England, 1878, professor of clinical gynecology at the Faculty of Medicine of the University of Bishop College at the time that institution was absorbed into the Faculty of Medicine of McGill University in 1906, at different times professor of medical jurisprudence in the University of Bishop College surgeon-in-chief to the Samaritan Hospital for Women, gynecologist to the Montreal Dispensary, surgeon to the Western General Hospital, consulting gynecologist to the Woman's Hospital in 1888 assistant editor and later editor of the *Canada Medical Record* aged 81, died, April 5

Jefferson D Southard @ Fort Smith, Ark, University of Louisville (Ky) Medical Department, 1886, member of the Radiological Society of North America, fellow of the American College of Surgeons, past president and secretary of the Sebastian County Medical Society, for many years president of the city board of health, for many years a member of the board of trustees of the Arkansas Tuberculosis Sanatorium, on the staff of the Sparks Memorial Hospital, aged 76, died, May 9, of melanoma

James Knox Simpson, Jacksonville Fla, University of Pennsylvania School of Medicine, Philadelphia, 1909 member of the Florida Medical Association, Southern Surgical Association and the Southeastern Surgical Congress, fellow of the American College of Surgeons, past president of the Duval County Medical Society, served during the World War, on the staffs of the Duval County Hospital and St Luke's Hospital aged 50, died, May 19, of coronary sclerosis and vascular hypertension

Archibald Henry Barkley @ Lexington, Ky Columbia University College of Physicians and Surgeons, New York, 1896 member of the House of Delegates of the American Medical Association in 1914, fellow of the American College of Surgeons, veteran of the Spanish-American and World wars, consulting surgeon to the Good Samaritan Hospital and surgeon to St Joseph's Hospital aged 64, died, June 1, of angina pectoris

Douglas Brown @ Castle Point, N Y College of Physicians and Surgeons Medical Department of Columbia College, New York, 1894 fellow of the American College of Physicians, served during the World War, on the staff of the Veterans Administration Facility aged 68, died, June 6 of chronic nephritis and myocarditis

John A Weidman @ Dunkirk, N Y, University of Buffalo School of Medicine 1901, for many years a member president and secretary of the school board, fellow of the American Col-

lege of Surgeons, on the staff of the Brooks Memorial Hospital, aged 69, died, May 11, of cellulitis of the left hand and streptococcal septicemia

Stricker Coles * Bryn Mawr, Pa., Jefferson Medical College of Philadelphia, 1892, formerly assistant professor of obstetrics at his alma mater, at one time on the staffs of the Philadelphia Lying-in Hospital, Jefferson Hospital and the Philadelphia Hospital, aged 70, died, June 20, of cerebral hemorrhage

J M Raphael Trudeau, Montreal, Que., Canada, Laval University Medical Faculty, Montreal, 1894, Laval University Faculty of Medicine, Quebec, 1895, associate professor of gynecology at the University of Montreal Faculty of Medicine, on the staff of the Notre Dame Hospital, aged 68, died, May 1

Charles A Currie * Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1880, for many years on the staff of the Germantown Dispensary and Hospital, formerly police surgeon to the Germantown district, aged 81, died, June 1, of arteriosclerosis and myocarditis

John Joseph Cadigan, Boston, Harvard University Medical School, Boston, 1899, head of the Latin department of the Boston Latin School, formerly member of the city board of health, aged 66, died, June 4, in St Elizabeth's Hospital, of carcinoma of the bladder and uremia

Edward Joseph Brett, Rutland Heights, Mass., John A. Creighton Medical College, Omaha, 1895, served during the World War, on the staff of the Veterans Administration Facility, aged 70, died, May 23, in the Holden (Mass.) District Hospital, of carcinoma of the colon

William Francis Smith * Atchison, Kan., Ensworth Medical College, St. Joseph, Mo., 1909, served during the World War, on the staff of the Atchison Hospital, aged 52, died, May 1, in St. Joseph's Hospital, St. Joseph, Mo., of heart disease and arteriosclerosis

Charles W Whaland, Chestertown, Md., University of Pennsylvania Department of Medicine, Philadelphia, 1874, member of the Medical and Surgical Faculty of Maryland, past president and secretary of the Kent County Medical Society, aged 87, died, May 6

Jesse Morton Barfield, Lineville, Ala., Atlanta College of Physicians and Surgeons, 1901, member of the Medical Association of the State of Alabama, served during the World War, aged 57, died, June 4, in the Citizens' Hospital, Talladega, of cerebral hemorrhage

Nathan Billings Colvin, Pontiac, Mich., University of the City of New York Medical Department, 1882, member of the Michigan State Medical Society, past president of the Oakland County Medical Society, aged 80, died, June 1, of chronic pulmonary tuberculosis

Edward Alexander Runyan, Linden, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887, member of the Michigan State Medical Society, aged 73, died, May 4, in the Hurley Hospital, Flint, of cerebral hemorrhage

Alexander Clyde Hunter * West Alexandria, Ohio, Miami Medical College, Cincinnati, 1903, past president of the Preble County Medical Society, for many years a member of the local school board, aged 59, died, May 15, of coronary occlusion

Jonathan Mackie Smith * Dunbridge, Ohio, Western University Faculty of Medicine, London, Ont., Canada, 1901, aged 63, died, May 7, in the University Hospital, Ann Arbor, Mich., of complications following an operation for gallbladder disease

Frederic Warren Conley, Van Wert, Ohio, Eclectic Medical College, Cincinnati, 1913, member of the Ohio State Medical Association, served during the World War, on the staff of the Van Wert Hospital, aged 51, died, June 4, of heart disease

Walter E Bartlett, Belle Plaine, Kan., St. Louis College of Physicians and Surgeons, 1893, member of the Kansas Medical Society, past president of the Sumner County Medical Society, aged 67, died, June 7, of coronary occlusion

George Arthur Zieg, Pittsburgh, University of Pittsburgh School of Medicine, 1909, member of the Medical Society of the State of Pennsylvania, on the staff of the Passavant Hospital, aged 52, died, May 8, of chronic nephritis

Ralph Spencer Stryker * Ridgefield, Wash., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, veteran of the Spanish-American and World wars, aged 58, died, May 26

David Blackstone Fields, San Francisco, Tulane University of Louisiana Medical Department, New Orleans, 1893,

served during the World War, formerly health officer of Trinity County, aged 67, died, May 28

Jorgen G Vigen, Los Angeles, University of Minnesota College of Medicine and Surgery, Minneapolis, 1894, aged 77, died, May 1, in Fergus Falls, Minn., of hypertension, arteriosclerosis and cerebral hemorrhage

William Wellford Wilson, Aurora, Ill., University of Maryland School of Medicine, Baltimore, 1921, member of the Illinois State Medical Society, aged 42, was instantly killed May 27, in an automobile accident

Jotham Freathy Black, Painesville, Ohio, Cleveland College of Physicians and Surgeons, Medical Department of Wesleyan University, 1898, aged 66, died, May 30, in a local hospital, of cerebral hemorrhage

Frank Blish Carpenter, New York, University of the City of New York Medical Department, 1881, member of the Medical Society of the State of New York, aged 84, died, June 5, of pulmonary tuberculosis

John Morris Summerill, Penns Grove, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1885, member of the Medical Society of New Jersey, aged 83, died, May 11, of heart disease

Joseph Martin D'Agostino, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1932, aged 30, died, June 16, in St. Agnes Hospital, of acute gangrenous appendicitis

John Thompson Bowers * Bemidji, Minn., Northwestern University Medical School, Chicago, 1908, on the staff of the Lutheran Hospital, aged 54, died, May 19, of coronary thrombosis

Charles Michael Cunningham, Mayfield, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1932, aged 30, died, June 10, in St. Joseph's Hospital, Carbondale, of pneumonia

Herman Robert White, New Haven, Conn., Yale University School of Medicine, New Haven, 1912, aged 48, died, May 14, in a local hospital, of burns received in an explosion

Alvar Anderson, Chicago, Northwestern University Medical School, Chicago, 1932, on the staff of St. Joseph's Hospital, aged 32, died suddenly, June 23, of barbiturate poisoning

Harry Carson Coe * Oakland, Calif., Stanford University School of Medicine, San Francisco, 1922, served during the World War, aged 46, died, June 11, of pneumonia

James Edwin Watson, Alton, Ill., American Medical College, St. Louis, 1894, member of the Illinois State Medical Society, aged 69, died, May 10, of heart disease

Frederick Leslie Beer, London, Ont., Canada, Western University Faculty of Medicine, London, 1905, aged 68, died, May 2, of coronary thrombosis and hypertension

Frederick William Risser, Strasburg, Ill., St. Louis Medical College, 1886, aged 74, was found dead, May 7, of cerebral hemorrhage and arteriosclerosis

Charles Benjamin Ziegler, Baltimore, Washington University School of Medicine, Baltimore, 1876, aged 81, died, May 5, of carcinoma of the prostate

William W Watkins, Clemson, S. C., University of Maryland School of Medicine, Baltimore, 1883, aged 84, died, May 1, of heart disease

Joseph William Zeh, Chicago, Chicago College of Medicine and Surgery, 1909, aged 64, died, May 12, of a self-inflicted bullet wound

George Eliot Watts, Los Angeles, University of Oregon Medical School, Portland, 1895, aged 62, died, May 20, of heart disease

Frank Edwin Adams, Piqua, Ohio, Cleveland Homeopathic Medical College, 1899, aged 62, died, May 19, of cerebral hemorrhage

James Slamovitz, New York, Eclectic Medical College of the City of New York, 1905, aged 53, died, May 14, of chronic endocarditis

Edwin D Stoddard, Beverly Hills, Calif., Chicago Medical College, 1875, aged 87, died, May 27, of arteriosclerosis

Osmar K Wolf, Marshfield, Ore., Willamette University Medical Department, Salem, 1907, aged 60, died, May 9

Oliver Frank Welch, Westport, Ind., Hospital College of Medicine, Louisville, Ky., 1897, aged 65, died, May 11

J M Carney, Elizabeth, W. Va. (licensed in West Virginia in 1881), aged 85, died in June, of senility

Robert Berlinger, New York, Long Island College Hospital, Brooklyn, 1884, aged 74, died, May 8

Udga, Inc. through the medium of "Fraser's News," prints purported copies of numerous letters claimed to have been received from persons who had taken "Udga Treatment" and

received relief from various ailments. According to the Federal Trade Commission's findings, "the majority of such persons were not capable of diagnosis or of determining whether the treatment brought about cures."

A fulsome puff for Udga Tablets is attributed to Dr. Walter R. George, who, according to "Fraser's News," was at one time health commissioner of Marion County, Indiana. "To quote Dr. George's own statements: 'It has been my privilege to review the Udga Tablet formula. While I but rarely endorse a medicine of any kind, I feel justified in making an exception in this case. I find Udga of pronounced value.'"

Dr. Walter R. George, "for many years Health Director of Indianapolis," was an endorser of the "patent medicine" "Cystex" (Bureau of Investigation, *THE JOURNAL*, June 9, 1934, p. 1959). And Dr. Walter R. George, "former Health Commissioner of Marion County" and also described as "for many years health commissioner of Indianapolis," some years ago was approving the "patent medicine" "Sargon" for indigestion, dizzy spells, headaches, etc. (*THE JOURNAL*, July 26, 1930, p. 285, Jan. 3, 1931, p. 57, and Sept. 30, 1933, p. 1093).

Although Mr. William Fraser boosts the Udga concoction under a thousand different captions, he apparently did not see fit to intervene in behalf of his remedy in the New Jersey action. On Sept. 7, 1935, no claimant having appeared, judgment of condemnation was entered and the twenty boxes, thirty-five bottles and 100 sample packages of Udga Tablets were ordered destroyed by the United States District Court for the District of New Jersey.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Sengarian Ointment (Formerly Hungarian Ointment)—Aschenbach & Miller Inc., Philadelphia. Composition: Essentially a lead soap containing rosin and camphor. For sciatica, erysipelas, cholera, catarrh, etc. Fraudulent therapeutic claims.—[*N. J.* 24073, November 1935.]

Michael's C P Tablets—C P Co., Frankfort, Ind. Composition: Acetanilid (2.8 grains per tablet), caffeine (0.3 grain per tablet), baking soda and celery seed. For fevers, rheumatism, cramps, etc. Fraudulent therapeutic claims.—[*N. J.* 24080, November 1935.]

Hemo Liver—Hemoliver Products Co., Hoboken, N. J. Composition: Essentially liver extract, a phosphate, sodium glycerophosphate, alcohol and water. For anemia, etc. Fraudulent therapeutic claims.—[*N. J.* 24081, November 1935.]

Dee Em Capsules—Dee Em Laboratories, New York. Composition: Essentially acetphenetidin (11 grains), aspirin (18 grains), phenolphthalein (0.26 grain) and ephedrine sulfate (0.05 grain per capsule). For colds, la grippe, asthma, etc. False and misleading claims.—[*N. J.* 24082, November 1935.]

Sylvester's Genuine Haarlem Oil (Waanning Tilly Bros., Haarlem, Holland)—M. Coward, Brooklyn, N. Y. Composition: Essentially a sulfonated fatty oil and turpentine. For stomach, blood and skin disorders. Fraudulent therapeutic claims.—[*N. J.* 24086, November 1935.]

Inthol—Inthol Co., Inc., New York. Composition: Essentially volatile oils including eucalyptus, pine needle, lavender and turpentine (60 per cent) and about 40 per cent of alcohol. For pneumonia, bronchitis, rheumatism, etc. Fraudulent therapeutic claims.—[*N. J.* 24090, November 1935.]

Red Circle Pills—James F. Stras, LaCrosse, Wis. Composition: Essentially mercury laxative plant drugs, calcium carbonate, an iron compound and a small amount of emetine. For liver, kidney and stomach disorders. Fraudulent therapeutic claims.—[*N. J.* 24091, November 1935.]

Oxy Indian Cough Syrup—O. H. D. Co., Inc. and Lacy R. Oxendine, Wilmington, Del. Composition: A concentrated solution of sugar and water in glycerin containing 1.43 per cent of alcohol and 1.90 minims of chloroform per fluid ounce with menthol and what was indicated as horse hound extract. Fraudulent therapeutic claims.—[*N. J.* 24100, November 1935.]

Correspondence

PLANTAIN HAY FEVER

To the Editor—Following the appearance of our article in *THE JOURNAL*, May 1, page 1500, we received a letter from O. C. Durham questioning the identification of the so-called common plantain used in our experiments. He stated that he had never been able to obtain common plantain pollen either from collectors of pollen or from atmospheric pollen studies; furthermore, that English plantain was the only type that could possibly contaminate the air.

In an effort to clarify this situation and to identify our pollen, labeled common plantain by collectors, we forwarded several slides to him for identification. Microscopic study of these slides revealed our English plantain to be English plantain but our common plantain turned out to be Rugel's plantain (*Plantago rugelii*).

This would tend to confirm Mr. Durham's experience, namely, that common plantain is a poor pollen producer and that practically no common plantain pollen is obtained in atmospheric studies.

The cross reactions and neutralizations noted in our original experiment should be corrected in view of these developments and made to read English and Rugel's plantain instead of English and common plantain. This change does not however in any way affect the practical aspects of this problem as contained in the original paper.

GEORGE I. BLUMSTEIN, M.D.
LOUIS TUFT, M.D.

THE FILAMENT-NONFILAMENT COUNT IN RHEUMATOID ARTHRITIS

To the Editor—The article by Short, Dienes and Bauer on "Rheumatoid Arthritis: A Comparative Evaluation of the Commonly Employed Diagnostic Tests" (*THE JOURNAL*, June 19) is a timely and much needed study of an important phase of arthritis. Unfortunately, the discussion of the immature polymorphonuclear count, in which the authors appear to use the terms "Schilling count" and "filament nonfilament count" synonymously, may prove confusing to your readers. They group the results of various reports on the young polymorphonuclear counts in arthritis without comment on the differences in technique and significance and state, for example, that in respect to Schilling or filament-nonfilament counts, conclusions are not unanimous, with results ranging from 52 per cent to 68 per cent, 78 per cent and 91 per cent to 100 per cent. A similar lack of clarity in considering these diagnostic polymorphonuclear counts in another recent publication (Cecil, R. L., *The Diagnosis and Treatment of Arthritis*, New York, Oxford University Press, 1937) leads us to point out the differences in these procedures.

The filament-nonfilament count is based on the principle that "if there is any band of nuclear material connecting the parts of a nucleus that nucleus for the purposes of the count cannot be said to be divided" and is therefore a nonfilament cell. Such a classification brings into the immature group of nonfilament cells many polymorphonuclears which in the Schilling count, by virtue of their partial segmentation must be placed in the mature count. Obviously, the normal limit of the nonfilament cell count therefore is higher (16 per cent) than that of the young cell count of Schilling (8 per cent). By elevating the normal level the nonfilament count gives a more flexible and more sensitive criterion for diagnosis involving only two types of cells, the filament and nonfilament. This count is simpler in performance and interpretation. While the same fundamental principle, a diagnostic immature cell count,

is involved, in the Schilling and filament-nonfilament counts, the technique and actual figures of each method are so different as to make synonymous reference to the tests especially confusing and inexact in any authoritative discussion.

A point of interest in the paper by Short, Dienes and Bauer is the abnormal Schilling count in 87 per cent of their patients with rheumatoid arthritis, as compared with positive sedimentation rates in 92.2 per cent of the group. These figures for the Schilling count are the highest reported to our knowledge, excepting one other study (91 per cent) in which the results are vitiated by the failure to separate the types of arthritis, the next highest values reported (Steinberg, 1935) were 78 per cent. We have found the filament-nonfilament count the most sensitive index to infection, positive in 96 per cent of a group of 100 rheumatoid arthritis, as indicated in our final report on the subject in *THE JOURNAL*, April 25, 1936, p. 1448.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DIAGNOSIS OF ADDISON'S DISEASE

To the Editor—1. Is there any laboratory or clinical test that is considered pathognomonic for Addison's disease? 2. What is the routine of treatment for an early case of Addison's disease? M.D., Michigan

ANSWER—1. The response of the patient to a salt-poor diet is often a specific diagnostic test in cases of Addison's disease. On abstaining from salt for a few days or a week or two, the patient develops increasing weakness, anorexia, nausea and possibly vomiting, loss of weight, fall in blood pressure, tachycardia and other signs of impending circulatory collapse. Most important, because entirely objective, is the striking decrease in the serum sodium concentration (Loeb, R. F. *Proc Soc Exper Biol & Med* 30:808 [March] 1933). Instead of the normal value of from 135 to 145 milliequivalents per liter (from 310 to 333 mg per hundred cubic centimeters) the serum sodium falls to 125 milliequivalents or less (287 mg or less). The serum chloride is also reduced while the nonprotein and urea nitrogen of the blood rise. These changes are brought about by the inability of the kidney to hold back sodium and water in the absence of an adequate amount of adrenal cortical hormone in the body. Dehydration results. The patient should be observed closely during this test, preferably in a hospital, because of the severe effects of salt restriction in some people. It is not yet known how early in Addison's disease the test becomes positive. Therefore failure of the serum sodium to drop after a salt-poor diet is given does not necessarily rule out the disease. If long standing tuberculosis of the adrenals has caused adrenal insufficiency, x-ray films of the abdomen may show calcification in the adrenal regions but areas of calcification may occur in normally functioning adrenals.

2. The treatment for an early case of Addison's disease is based on the known functions of the adrenals. The patient must be carefully guarded against exposure to cold or heat, infections, emotional shocks, overexertion, anesthesia and surgical procedures except in an emergency. Any hemorrhage may be serious. Epinephrine, insulin, solution of posterior pituitary and other powerful drugs may cause dangerous reactions even in small doses. Any excessive loss of fluid from the body as in diarrhea, sweating or vomiting may precipitate a so-called crisis or shocklike state if not immediately compensated by adequate salt and water intake. As a routine the patient should take from 7 to 12 Gm of sodium chloride daily in capsules in addition to a liberal use of salt in and on food. The daily administration of a few grams of sodium bicarbonate or sodium citrate is favored by some clinicians. If nausea prevents the oral ingestion of salt, the daily dose should be given by rectum or under the skin. The maintenance of body weight and a general feeling of well being indicate an adequate salt intake. The use of a potent adrenal cortex extract is advisable, this is especially true for preoperative and post-

operative therapy and for other emergencies. However, commercial adrenal cortex preparations leave much to be desired at present. Pregnancy should be forbidden. During mild respiratory or other infections, the patient with Addison's disease should be watched as closely as one with severe diabetes and the salt intake kept up at a level of from 15 to 20 Gm daily by any feasible route of administration.

COPPER COMPOUNDS IN TUBERCULOSIS

To the Editor—Will you kindly forward to me a list of references concerning 'Copper Morphuate' and whatever literature you may have on this product in the treatment of pulmonary tuberculosis as well as your own opinion of it? M.D. New York

ANSWER—In 1885 and again in 1894 (Steinheil, G. *Traitément de la tuberculose par les sels de cuivre*, Paris, 1894) claims were made for the specificity of copper in the treatment of tuberculosis. The administration of copper was reported to produce both local and general reactions, such as one observes when tuberculin is used therapeutically. For the most part copper phosphate or acetate was administered. The workers of that time were of the opinion that copper had essentially the same effect in the treatment of tuberculosis as mercury in syphilis.

In 1912 another worker, von Linden (*München med Wchschr* 59:2560, 1912) reported the results of copper on the tubercle bacillus. She showed that, when copper was uniformly distributed in mediums, the clumps of tubercle bacilli later presented a green color. She believed that this indicated that copper was specific for tubercle bacilli since no other micro-organisms included in her studies showed the green color. Moreover, she found that the copper killed tubercle bacilli. In guinea-pig experiments von Linden reported that tuberculosis in animals became more chronic following administration of copper and that some animals did not die of tuberculosis.

Strauss (*Beitr z Klin d Tuberk* 34:107, 1915) reported good results following the administration of copper to persons suffering from lupus. During the next few years, such workers as Mayer (*Beitr z Klin d Tuberk* 32:211, 1914), Kaiser (*Therap Monatsh* 28:748, 1914), Eggers (*Beitr z Klin d Tuberk* 47:373, 1921) and Klopstock (*Ztschr f Tuberk* 41:119, 1924) did considerable work on the effects of copper in the treatment of tuberculosis in both animals and human beings. These workers came to the conclusion that but little benefit to the patient is derived from the use of copper. Moreover, they were unable to obtain any evidence that it is specific for tuberculosis.

DeWitt and Sherman (*J Infect Dis* 15:245, 1914) found that a concentration of 5 per cent copper chloride is necessary to kill tubercle bacilli spread out in a thin layer in twenty-four hours. If clumps are present, even a 25 per cent preparation does not kill the bacilli in this length of time. However, the growth of tubercle bacilli in culture was found to be inhibited by a preparation of copper chloride of 1/100,000.

Corper (*J Infect Dis* 15:518, 1914) made an extensive and painstaking study of the effects of copper on tuberculosis in animals. He used several simple copper salts but he observed no significant effect on the course of the disease. Moreover, at postmortem examination no copper was to be found in the areas of tuberculosis or in the pus removed from the lesions. Corper also used colloidal copper but concluded that in all forms in which copper was administered it had no effect on the disease. Moreover, he found that no matter what form of copper is administered it does not reach the tissues as a salt but as colloidal copper. In this form it was believed impossible for it to enter the tissues that have been necrotized by tuberculosis.

MacDowell (*Am Rev Tuberc* 25:252 [Dec] 1932) has employed colloidal copper morphuate and reports no toxic effects such as may occur when gold compounds are administered. Moreover his results are identical with those obtained following the administration of gold compounds. MacDowell does not consider copper a specific in tuberculosis. He introduces colloidal copper morphuate into the blood stream every two days beginning with 5 cc, up to an optimal dose of 10 cc. MacDowell has also devised a technique for introducing copper morphuate directly into pulmonary cavities.

Although it seems to have been proved conclusively that copper in the concentration in which it can be administered to the tuberculous patient even though it reaches the lesion, does not have a germicidal effect and that it can in no way be regarded as a specific for tuberculosis nevertheless an occasional investigator still becomes enthusiastic about new compounds.

Other references on various phases of copper therapy are as follows: *Am Rev Tuberc* 6:929 [Dec] 1922; *München med Wchschr* Jan 11, 1924; *Lancet* 1:1297 [June 28] 1924; *Rev*

belge d tuberc 17 1 [Jan] 1926, *Rev tuberc* 9 898 [Dec] 1928, *Deutsche med Wchnsch* 15 108 [June 28] 1929, *Brit J Tuberc* 24 134 [July] 1930, *Ztschr f Immunitätsforsch* 78 173 [Jan 30] 1933, *Medicina Mexico* 15 358 (July 25) 1935, *Rev Asoc med Argent* 49 527 (April) 1935, *Rev brasil de tuberc* 5 1 (Nov-Dec) 1935, *Prensa med argent* 21 1312 (July 11), 1350 (July 18) 1934, *Semana med* 1 1749 (June 7) 1934, *Gaz clin* 31 329 (Dec) 1933

Wells and Long (The Chemistry of Tuberculosis, Baltimore, Williams and Wilkins Company, 1932) make the following statement concerning copper therapy "In all probability, as far as copper is concerned, it acts alike in all compounds and preparations, and any different action is due to the other radical of the compound and not to the copper. It may, like so many other drugs, have a hyperemic or inflammation-exciting action on the tubercle which in some cases may react favorably on the tubercles, as does tuberculin. But it is more toxic and not more favorable than the tuberculin and in these cases tuberculin may better be used."

PROMOTING BONE FORMATION

To the Editor—March 9 1936 a 19 year old girl was brought in following an automobile accident suffering from a transverse fracture of the middle third of the left femur with considerable shortening and external rotation of the lower fragment. The leg was placed in extension for several days after which a reduction was made by means of the modified Roger Anderson method. An ambulatory cast was applied. On the third day following the application of the cast the patient was walking about the hospital with the aid of a cane. Check-up roentgenograms showed that the reduction was excellent. The cast was left for eight weeks and subsequent roentgenograms revealed no callus formation of any kind whereupon the cast was allowed to remain four more weeks when further roentgenograms were taken which still showed no evidence of any union or callus. The patient received blood transfusions during this time because of secondary anemia. She received cod liver oil with viosterol and dicalcium phosphate all in large doses. After twelve weeks pins in the cast and bone were removed and a spica cast was applied which remained for six weeks more. There was no callus and an open operation was resorted to in July 1936. A Lane plate was inserted and the ends of the bones at the fracture site were freshened up. At the operation it was noted that there was absolutely no evidence of any union. The patient received the previously mentioned medications gained weight had good color felt well and all laboratory and objective examinations were negative with the exception of a family history her sister having had the same trouble in getting a fracture to heal. The patient was given splenic extract intramuscularly in an attempt to stimulate the growth of bone. Never at any time has there been any infection or any drainage from either the pin wound or the subsequent surgical wound all of which closed cleanly within ten days. The Lane plate was left until Jan 1 1937 when further roentgenograms showed little if any union and absolutely no callus at the site of the fracture. In view of this a bone graft was undertaken. Intra medullary insertion of a splinter of bone taken from the tibia was made at the site of the fracture. At the time of operation which was two weeks ago it was interesting to note that the Lane plate was very firmly attached all six screws holding their thread firmly in the bone. There was union of the bone although this was not noted in the roentgenogram, and the site of the fracture could not be definitely distinguished. But the bone at this place could be cut easily with a scalpel the bone being very soft and fibrous. In view of this fact the bone was not refractured but a trough was chiseled away large enough to allow the tibial transplant to be inserted. The wound was closed and a spica cast applied which has healed cleanly with no drainage fifteen days after the operation. I tried everything I could find in the literature, including ultraviolet radiation in an attempt to stimulate the union and callus formation. I would appreciate any information to aid the deposition of calcium and bone in this case. Please omit name and address.

M D North Dakota

ANSWER—Metallic plates and screws do not stimulate osteogenesis, and it is probable that with their removal on January 1 a more rapid production of callus will take place.

No medication of any kind has been demonstrated to have any effect in promoting bone formation, provided the blood calcium and phosphorus are within normal limits. Pulverized bone and venous blood have been injected at the site of fracture without noteworthy results.

The best form of stimulation is the promotion of function in the fractured bone. The correspondent states that union was present at the time of removal of the Lane plate but that the bone was abnormally soft. A Thomas caliper splint should be applied to the fractured leg, with a high soled shoe on the right foot and the patient should be encouraged to walk with crutches, bearing a portion of the body weight on the ball of the foot. The heel should not bear any weight, so the caliper must be about 1½ inches longer than the left leg. The high sole and heel for the right foot should be 2 inches high. It may be wise to apply wooden or aluminum coaptation splints around the femur, to aid in preventing angulation.

As the fracture becomes more solid, the amount of weight bearing may be increased, the progress being checked by x-ray examinations at intervals of three or four weeks.

BRONCHIAL ASTHMA

To the Editor—A white man aged 33 contracted an infection of the upper respiratory tract which consisted mainly of malaise and a rhinitis. This persisted for two weeks when he was seized with severe pain in the left frontal sinus. At this time the temperature was 99 F. respirations were not labored, the pulse was good the heart was normal the lungs were filled with musical rales and expiration was prolonged. In conservative therapy consisting of ephedrine and local heat the sinusitis has improved. The patient for the past two weeks has complained of a cough particularly at night. He also observes for the first time wheezing on expiration. At one time he received a hypodermic injection of 0.5 cc of 1:1000 epinephrine solution with improvement in the wheeze for twenty minutes. Ephedrine in a dosage of three-eighths grain (0.025 Gm.) three times a day has not improved the condition. Codeine and papaverine one fourth grain (0.016 Gm.) of each (two before bedtime) has not given relief. The patient's father is said to be asthmatic. Do you think this is an early case of asthma? The patient has not had any attack of dyspnea. What should be the future course of therapy? Please omit name.

M D New York

ANSWER—The history and course are definitely suggestive of bronchial asthma. From the information at hand one cannot be sure whether this is a case due to extrinsic (food, inhalant) causes or to bacteria. The latter is more likely in view of the fact that it seemed to follow directly the advent of a respiratory infection and sinusitis. It is also possible, of course, that the asthma is due to allergic causes but was merely precipitated or is aggravated by the bacterial infection. It is, of course, necessary to take care of the infection by conservative means. If it has been ascertained that active infection is no longer present, it may be assured, at least temporarily, that one is dealing with a purely allergic asthma. Cutaneous tests with a comprehensive list of foods and inhalant allergens should be made. If the latter are negative, intracutaneous tests are indicated. If positive reactions are found, one should be guided in the therapy by them. If no reactions are obtained and other observations indicate that the patient may not be allergic, vaccine therapy, preferably autogenous, should be tried.

For palliative treatment the inhalation of a very fine spray of 1:100 solution of epinephrine hydrochloride is usually efficacious in the milder attacks and may be used fairly frequently. The solution must be vaporized in a special atomizer so that no droplets are present. Iodides in 10 grain (0.65 Gm.) doses three times a day usually result in improvement. Inhalation of the fumes of a mixture of burning saltpeter and stramonium will usually give quick relief. It should be remembered, however, that the measures are only temporary and that for more permanent results the cause for the asthma must be sought.

X-RAYS AND RADIUM IN CANCER OF CERVIX

To the Editor—I should greatly appreciate your opinion and that of the consensus of radiologists on the value of roentgen rays following the application of radium in the treatment of carcinoma of the cervix. If advisable how much treatment is usually given and when may a patient discontinue treatments if there is no gross sign of recurrence? The use of radium in early cases is of course, generally accepted but I believe there is some difference of opinion regarding the x-ray therapy follow up.

M D Illinois

ANSWER—The consensus of radiologic opinion concerning treatment for carcinoma of the uterine cervix is that under ordinary circumstances the combined use of radium and roentgen rays yields the best results. When both radium and roentgen rays are used, the opinion of most workers is that the roentgen treatment should be given first, preferably by the method known as fractional irradiation. In the case of carcinoma of the uterus, this requires daily exposure to a comparatively small dose for from thirty-five to fifty days. The aim of the procedure is to inhibit or destroy malignant cells outside the uterus, either in the broad ligaments or in the pelvic lymphatics. An advantage of the method is that, by the time roentgen irradiation has been completed, the primary tumor has already retrogressed to some extent and treatment with radium is facilitated. Another advantage is that when secondary infection is present preliminary roentgen irradiation may diminish this considerably. Some radiologists still use roentgen therapy after the radium treatment, but the weight of opinion favors roentgen treatment before radium, whenever possible.

How much treatment is necessary depends on the circumstances in each case. Even with radium, the present tendency is to use fractional treatment by inserting into the cervical portion of the uterine cavity a small quantity of radium, which is left in place for a considerable number of days. Some use a larger quantity and allow the radium to remain in place for from twelve to fourteen hours at a time two or three times a week for two or three weeks. The total dose varies accordingly to the method of application from 6,000 to 15,000 milligram hours or more, and further treatment is not given unless a relapse until recurrence develops.

PHYSIOLOGY OF SLEEP

To the Editor —1 Please give the evidence that the first few hours of sleep are the most restful of the entire night. 2 If one slept in three two hour periods interrupted by two ninety minute periods of wakefulness would each of the periods of sleep be equal in restfulness to the first? Would such a program be deleterious to health in any way?

M D New York

ANSWER—1 There is little reliable information of any kind save as to subjective evidence of certain sleepers. The work in the Munich clinic on sleep and fatigue gives no consistent reports. There are too many variables in individual cases to give any broad generalization, further than saying that the deeper the sleep the greater the probability of restoration in the body.

2 The program outlined seems in contradiction to much that is known of sleep and recovery from fatigue. Certain probably fictitious stories tell how certain notable persons, Napoleon for instance, could sleep for an hour or two at any time and be entirely rested. Sound sleep and restitution are intimately related but are highly individual situations. Some few individuals seem to be able to get along on the most fantastic sleep rituals, but for the average from six to eight hours of uninterrupted sleep seems to work best.

LIGHT AND VISION

To the Editor —I have undertaken to determine whether the lighting in the dormitories is proper and conducive to study and good health. There has been considerable discussion among the students as to the proper amount of light in a room of $14\frac{1}{2}$ by $12\frac{1}{2}$ feet with an $8\frac{1}{2}$ foot ceiling. These rooms are painted in a buff or cream color. Each room is shared by two students. I would sincerely appreciate any statistics or information concerning the candlepower or wattage that should be sufficient in such a room.

RICHARD V RIDDELL Fayette Mo

Lights in dormitory. A A side brackets 6 feet high. B light suspended 4 feet from ceiling with reflector, C C closets.

ANSWER—If the location of desks and windows had been shown in the drawing of the dormitory room, more specific recommendations could have been made for the lighting of the room. However general suggestions concerning the lighting of the room might be as follows.

It is suggested that the wall brackets be discontinued as a method of providing seeing illumination for study purposes. Outlet B might be equipped with an indirect unit

mounted relatively close to the ceiling utilizing a 150 watt Mazda lamp to provide a level of general illumination throughout the room. For study purposes it is recommended that each desk be provided with a suitable lamp equipped with not less than one 100 watt Mazda lamp. Not less than 20 footcandles should be provided on the work area where the studying is done.

SIGNIFICANCE OF WASSERMANN REACTION

To the Editor —Recently at our hospital a middle aged man came to the autopsy table with a rather advanced adenocarcinoma of the stomach. Before death the patient had a four plus Wassermann reaction on several tests. The personal and family history were negative for syphilis. There were no stigmas of syphilis. On the usual postmortem examination there was no evidence of syphilis. Was the repeated four plus serologic reaction caused by the adenocarcinoma? Please omit name.

M D New York

ANSWER—The Wassermann reaction is absolutely diagnostic of syphilis with the exception of yaws. The latter disease is also caused by a spirochete almost if not identical with the spirochete of syphilis. The Wassermann reaction is dependent on a particular antibody found in patients with syphilis and can be demonstrated by suitable lipoidal substances.

It is now believed that a positive Wassermann reaction is evidence of the presence of a syphilitic infection but that a negative reaction does not necessarily exclude the probability of syphilis. The antibody of syphilis is inconstant in a given case from time to time. The reaction becomes positive on about the tenth day of the primary stage and is positive in about 90 per cent in the preeruptive stage and in 100 per cent in the secondary or eruptive stage. In the tertiary and later stages, from 75 to 90 per cent yield a positive Wassermann reaction.

Although a positive Wassermann reaction indicates that a person is syphilitic, it by no means proves that a particular lesion is syphilitic. A syphilitic patient may have a nonsyphilitic peptic ulcer, a carcinoma, active tuberculosis or other disease that afflicts mankind. Syphilis is found in about 8 per cent of

patients, and may be coincidental with other diseases, such as carcinoma. Neoplasms alone do not produce a positive Wassermann reaction.

A routine postmortem examination without careful microscopic examination of the different organs does not exclude syphilis. A histologic diagnosis of syphilis requires the demonstration of *Spirochaeta pallida*. A serologic diagnosis by means of the Wassermann test or certain precipitation methods (the Kahn and others) is much easier to perform.

CHANGES IN SENSATION IN LEG AFTER HEAD INJURY

To the Editor —A man aged 22 a laborer while engaging in helping to build an engine house at a local mine was knocking down some planks and one hit him on the left side of the head and knocked him down. Physical examination revealed a badly lacerated tip of the left ear which was sutured. Lumbar puncture was done but it showed no pathologic change. He was in the hospital for four days during which time he made no complaints. He was then sent home and instructed to remain in bed. He was told to lie flat in bed without a pillow, and not to read or smoke. He complained of dizziness in his right ear but there was no discharge from the ear and this cleared up of itself in a few days. He disregarded the instructions however. Eight days ago when I went to see him at his home he complained of weakness and numbness in his left leg. Thinking that he may have injured this member originally but failed to pay much attention to it I had a roentgenogram of this limb taken but without result. At no time has there been an elevation of temperature or of blood pressure. He complains of tenderness over the site of the lumbar puncture. I might say that the roentgenograms of his head showed no pathologic change. What could cause the distress in his leg? What is the best treatment and what is the prognosis? Please omit name and address.

M D Michigan

ANSWER—There is no objective evidence submitted to indicate any cerebral injury, but this does not rule out the possibility of its occurrence in this case. The weakness and numbness in the left leg might be due to some local injury to the leg itself or lower part of the abdomen and back or to an edema of the right side of the brain in the distribution of the leg area in the precentral and postcentral convolutions. The latter cause is a rare possibility, because there is no evidence submitted suggesting either absolute or presumptive signs of cranio-cerebral injury. The following plan of treatment is suggested: absolute rest in bed in the hospital for ten days, 1 ounce (30 Gm) of magnesium sulfate by mouth on the first and third mornings of the ten day rest period, no visitors, symptomatic treatment for pain, sleep, examination of the rectum, genito-urinary system, lumbosacral spines and left hip. If at the end of this time no objective evidence of any abnormality is found, the man should be considered as having a functional disorder. The prognosis in any instance should be good.

PERFORATION OF SHRAPNELL'S MEMBRANE WITH VERTIGO ON SYRINGING DISCHARGING EAR

To the Editor —A lawyer aged 33 has suffered from a recurrent discharge from the left ear since 1932. The discharge is never profuse but he states that a week is the longest interval that it ceases. Very rarely he has pain in the left mastoid area aching in character and occasionally he feels slightly dizzy. Examination shows a small discharge rather foul smelling coming from a perforation in the upper part of the drum. Cochlear and vestibular function are normal in both ears. Vestibular testing caused marked pallor, sweating and nausea. Vestibular reactions of nystagmus past pointing and vertigo were normal. X-ray examination shows both mastoids to be dense and sclerotic. Otherwise his health is good. I have treated him conservatively for the past three years. However becoming discouraged he has consulted a prominent otologist who states that there is probably bone necrosis in the attic and antrum and he urges immediate mastoidectomy to avoid possible serious complications. Do you think he should undergo surgery? As a lawyer loss of hearing in one ear would be a serious handicap. There are many people who have running ears for years. Do you think there is usually the danger of a serious complication in these cases? At one time he syringed his ear with moderately warm water to remove the accumulated discharge immediately after he became so dizzy that he was confined to bed for twenty four hours. What significance do you place on this incident? I am anxious for your comment as to whether you do or do not recommend surgery.

M D New York

ANSWER—In this case there is probably perforation of Shrapnell's membrane. As a rule, if hearing is still fairly good, that is to say if an unaccentuated whisper with the opposite ear closed is heard more than 2 or 3 meters, one is loath to do a radical mastoid operation. On the other hand, when foul smelling secretion is present and there is headache or vertigo an operation is usually indicated. It is advisable to try conservative measures for a short time at least, namely, very careful irrigation with an attic syringe using warm 50 or 75 per cent alcohol. If after a few weeks the secretion does not diminish or some other untoward symptoms such as headache persist, a carefully performed radical or conservative

radical operation is indicated. If the hearing before the operation is fair, it is not likely that it would be entirely lost. In fact, in many instances there is only a moderate diminution in hearing postoperatively as compared with that before operation. It is quite true that many people have so-called running ears for many years. When there is a large central perforation it usually means that there is some involvement of the eustachian tube and here the operation is not urgently indicated, but when the discharge comes from the region of Shrapnell's membrane, when the perforation is marginal and when the bone is involved, it is not advisable to permit the discharge to continue indefinitely. As previously stated, if any symptoms such as vertigo or headache tend to recur and if the conservative measures fail, after proper preparation, usually including rest for several weeks until vertigo disappears, operation is indicated. If marked vertigo occurs following the use of an even fairly warm solution, it must be either entirely discontinued or only small amounts used without any undue pressure in the act of syringing.

TALIPES EQUINOVARUS

To the Editor—I am treating a case of congenital talipes equinovarus in an infant delivered at seven and a half months by cesarean section because of marginal placenta praevia. The infant is now 2 months old and weighs about 8 pounds (3 625 Gm). The birth weight was 5 pounds (2 265 Gm). Because of the prematurity and the frail condition of the infant treatment of the foot was confined to gentle manipulations followed by adhesive strapping. The manipulations are not apparently painful to the infant and at each treatment have given more and more correction of the deformity. The deformity of course does not stay corrected and is only partially corrected by the adhesive strappings. Manipulations now give almost complete correction and the infant is much stronger. In the use of plaster casts or other treatment what do you suggest? If you suggest casts, please outline the method of application and frequency of removal and duration of the use of casts. Please omit name.

M D Georgia

ANSWER—The baby has had good treatment except for maintenance of the correction, which has not been 100 per cent. The varus deformity should be corrected first and the equinus later, in order to avoid the production of a "rocker foot." A smoothly fitting plaster-of-paris cast made of bandages about 1½ inches wide and 2 feet long, should be applied over a stocking that fits the child. The child's stocking may be turned inside out so that no seams will touch the skin. There should be a small amount of sheet wadding applied and a layer of gauze to smooth it down. Before the cast is applied, the foot must be manipulated (while the outer malleolus is under constant protection, as the epiphysis can be injured by trauma). The cast should be changed every five to fifteen days, depending on the rate of growth of the child.

HYPERTROPHIC ARTHRITIS

To the Editor—One of my professional friends aged 58 has been complaining of pain and disability in the left hip joint for several weeks. The family and previous history are negative. General physical examination is negative. Blood examination including a Wassermann and urinalysis are both negative. X-ray examination shows bone proliferation on the upper lip of both acetabula more marked on the left side. Deposits are also scattered about both sacro-iliac joints. The last lumbar vertebra is displaced forward and downward toward the pelvis. The abdominal aorta is distinctly outlined by deposits throughout its wall. Numerous lymph nodes in both the abdomen and the chest are similarly involved. Treatment of the left hip has consisted of diathermy which has given considerable relief temporarily. In view of the x-ray examination there is more apprehension over the general situation shown than in reference to the hip joint itself. Apparently the problem has to do with general nutrition. Any suggestions you may be able to make with reference to the care of this case will be much appreciated. Please omit name.

M D New York

ANSWER—The diagnosis would seem to be hypertrophic arthritis of both sacro-iliac and lumbosacral joints and hips, with spondylolisthesis or forward slipping of the fifth lumbar vertebra and calcification of the abdominal aorta. It is possible that the condition is a hyperparathyroid syndrome which is producing "rheumatic pains." It will be of interest to have serum calcium and phosphorus determinations and chronaximetric examination.

It is difficult to give advice for this individual patient. A comprehensive study should include a thorough examination for foci, especially the teeth, throat, sinuses, gastro-intestinal, genito-urinary and respiratory tracts. The weight of the patient has not been given and his diet should be based on weight and blood determination, especially uric acid.

No mention has been made of a rectal examination to see whether the prostate and seminal vesicles are normal. Diathermy will probably give no lasting benefit. Smith-Petersen has recently advised acetabuloplasty to relieve this type of pain

in a hip. It is a plastic operation aimed at correcting the mechanical impingement of the head and neck against the acetabulum.

It is suggested that the patient be placed under the care of the best orthopedic surgeon in his locality to determine what measures should be taken.

QUINIDINE ELIMINATION

To the Editor—A woman aged 37 who has two children aged 17 and 10 both delivered by cesarean section with a rheumatic heart disease of long standing developed a rotary oscillation of the eyeball with some nausea and slight vomiting about one and one half years ago. She was seen by a neurologist who made the usual tests and said she had a brain tumor. She then was seen by a brain surgeon who told her she definitely had no brain tumor. Since then she has been much better but still has the oscillations and headaches on occasion. She was seen by an eye, ear, nose and throat specialist who gave her a clean bill of health as far as his specialty was concerned. This was last week. For her heart condition she was given 3 grams (0.2 Gm) of quinidine hydrochloride three times a day and she states that she took 150 tablets when this condition came on. The question is: Could the quinidine have produced this condition and what can be done for the treatment?

M D Massachusetts

ANSWER—Since quinidine is rapidly eliminated, it could not possibly exist in the system or continue to produce an effect for any such length of time. Unfortunately, treatment for this condition is of little avail.

ON THE ACID SIDE

To the Editor—Please explain the origin of the term "acid condition." Tell me its relation if any to pyorrhea, receding gums or skin disease. I hear the expression frequently from the public and it seems to be fostered by the "patent medicine" interests. Now I am acquainted with and urine acid, saliva acidosis, alkalosis and am greatly interested in the "holistic" problems but in no book in my library and I own many of the finest medical books printed can I find any reference to "acid condition." I note that dentists tell patients they have an acid condition and send them to the doctors to be cured. I will appreciate a complete discussion, as I have exhausted my resources in explaining the myth (?) to the public.

PHILIP J. LUKERS M D, Ambler, Pa.

ANSWER—The correspondent is entirely justified in his skeptical attitude toward the use of the term "acid condition." This term could be properly applied only to an uncompensated acidosis, which occurs relatively rarely and in illnesses of considerable severity. The interpretation of various common minor ailments as an "acid condition" is chiefly a result of the exploitation of the public by certain ignorant or unscrupulous promoters of proprietary preparations.

BISMUTH SUBSALICYLATE FOR FLAT WARTS

To the Editor—Please send me information with regard to the present use of bismuth subsalicylate injections for flat warts. If there is any other treatment being used I should be glad to hear about it.

MARGARET V. PIRSCH M D Kenosha Wis.

ANSWER—The treatment of palmar and plantar warts by the intramuscular injection of bismuth subsalicylate was reported by Lurie (*Arch. Dermat. & Syph.* 26:95 [July] 1932). Injections are given at weekly intervals intramuscularly in the upper outer gluteal quadrant. Children from 6 to 10 years of age receive 1 Gm., from 10 to 13 years 1.5 Gm., and older patients 2 Gm. From one to three injections sufficed in most cases. Of forty-nine cases treated, cure was established in thirty-four that were followed up, and no relapses were seen in the latter number one year after treatment. Warts about the nails were more resistant; those about the hands less resistant, and those on the feet responded most rapidly.

The use of superficial electrodesiccation, the cautery, in chloroacetic acid and x-rays are further methods of treatment. Radium may also be employed for single lesions or closely aggregated lesions.

LOW CALORY DIET AND VITAMINS

To the Editor—Have you information as to the amount of vitamins necessary to add to an extremely low calory diet in case of pituitary obesity?

M D Mar

ANSWER—Owing to the general flux in the state of vitamin requirements as well as the acknowledged instability and variability of vitamins, it is practically impossible to establish any standard amount of any vitamin necessary for such a case. Attention might be called to the fact that the caloric value of a diet is considered to be independent of the vitamin content. A high caloric diet such as in the case of typhoid or post duodenal ulcer is blatantly deficient in specific vitamins. An extremely low caloric diet might tend to be low particularly in vitamin D, which can be artificially augmented by the use of cholesterol.

Book Notices

Human Genetics and Its Social Import. By S. J. Holmes. Professor of Zoology in the University of California. Cloth. Price \$3.50. Pp. 414. With 84 illustrations. New York & London: McGraw-Hill Book Company, Inc. 1936.

The constitution of the individual patient at the moment of the physician's attention is the product of two factors, nature and nurture, or heredity and environment, or, as some one has facetiously expressed it, the devil and circumstance. Some may wish to limit the definition of constitution to the consequences of heredity alone, but heredity acts in an environment to which the individual is both susceptible and responsive. Ancestry determines the substrate but environment continuously influences this historical product of the race and is jointly responsible for its momentary status.

The reader of Professor Holmes's judicial and lucid presentation of the respective fields of influence of these two biologic factors which determine human nature will soon detect the author's profound belief in the potency of heredity and, as he reads, will find the increment of the evidence for this more and more convincing. However, he will also find that at least some of these expressions in human nature of the innate hereditary potentialities are not static but mobile. These contending factors, under the touch of the external factors which constantly impinge on the sensitive flesh of man, are nicely balanced in the chapters on nature and nurture and on heredity and environment. The book contains clear statements of the cellular basis of heredity, criticism of the inadequate evidence of the inheritance of acquired characters, Mendel's law, the evidence for the determination of sex at conception and the balancing of the male and female determinants in the phenomena of intersexuality, the interaction of factors, sex-linked factors, such as hemophilia and optic atrophy, and the kinds, causes of and measurement of variability.

Heredity in man is presented in the discussions of mental defects and diseases, crime and delinquency, and the marginal groups of society who make up the social problem people who enter so largely into the physician's problems of free medical service and are the group in which medical nostrums flourish. A special chapter on choices in mating analyzes the factors that underlie the consequences of such choices, some of which tend to perpetuate human defects such as deafness and susceptibility to tuberculosis. The causes of the widespread declines in the birth rate among occidental peoples and urban populations are analyzed and the dysgenic effects of the differential birth rate, revealed in the fact that the intellectual classes have too few children to maintain their numbers and that the most intellectual women marry infrequently and late in life, while those in social classes with a low intelligence quotient breed like rabbits. Current changes due not only to selective mortality but also to improvements in scientific medicine and to the social extension of medical service as well as to changes in birth rate are modifying the proportions of age classes in the population. These changes are in part at least, responsible for shifts in the incidence of disease of both childhood and old age and thus affect the content of medical services. The dysgenic effects of war and the growth of cities on man are discussed. The biologic consequences of the migrations of peoples on the characteristics of current and future populations are critically examined. Physicians will find the chapter on inbreeding and crossbreeding taken in conjunction with the discussion of the

heredity of human defects and the phenomenon of recessive characters, helpful in cases in which their advice is sought in cousin marriages.

There is much in this judiciously written presentation of human genetics to justify the physician in the practice of making full and adequate records of his patients' medical history. There is even fuller justification for society to reevaluate the significance and importance of the family physician.

Précis de parasitologie. Par E. Brumpt, membre de l'Académie de médecine, professeur à la Faculté de médecine de Paris. In two volumes. Fifth edition. Cloth. Price 200 francs per set. Pp. 1 108* 10*3 113* with 1 085 illustrations. Paris: Masson & Cie. 1936.

No book on human parasitology since the days of Leuckart's pioneer work *Die menschlichen Parasiten und die von ihnen herrührenden Krankheiten* (1863) has so ably supplied medical needs, filled so large a place in this specialized science, gone through so many editions or so completely kept down to date in this rapidly expanding field as has Brumpt's *Précis de parasitologie*, now in its fifth edition, more than twice the size of the fourth (1927). The grounds for this popularity are diverse. The most important among them is the direct application of the author's treatment to medical needs. In all cases in which clinically important parasites are discussed, and knowledge permits, the discussion includes not only morphology, classification and life history but also diagnosis, pathology, treatment, prognosis and prophylaxis. A second reason is the inclusiveness of the work, which covers all known parasitic infections of man except bacterial and virus. It includes spirochetes, protozoans, helminths, arthropods, the rarer parasitic representatives derived from other animal phyla, and the extensive and all too little known field of mycology. A third reason is the breadth of view of the author based on a wide and long experience as professor of parasitology in the Faculty of Medicine of the University of Paris, director of the Institute of Malariology of Paris, secretary general of the Institute of Colonial Medicine of France, and formerly professor of parasitology at São Paulo, Brazil. Extensive travel in the French colonies and elsewhere in the tropics has widened and diversified his contacts with these fertile fields of parasitic infection of man. His own researches in amebic dysentery, trypanosomiasis and malariology and in the field of animal vectors of human infections lends weight and breadth to his treatment of the subjects. Lastly, the book is superbly organized for practical use and is written with fine clarity of style and the unsurpassed lucidity to which the French language is so well adapted. The analytic table of contents fills no less than twenty-nine pages and the index forty-nine. The fifth edition has been entirely rewritten with the addition of 500 pages of text and with 35 new illustrations, of which 168 are original. Among the new discoveries included in this edition are the mode of transmission of certain spirochetes, the detection of the animal reservoirs of several relapsing fevers of man, the vectors and mode of transmission of cutaneous and visceral leishmaniasis, a much wider extension of human trypanosomiasis than had been suspected previously, great advances in mosquito control and malarial prophylaxis through the use of new drugs, the etiologic factors in four diseases of the Rickettsia group, and the receptivity of numerous mammals to yellow fever and the preparation of a vaccine.

No field of human parasitology is more obscure, more confused and less scientifically founded than that of human mycology. One of the chief values of this book is its critical treatment of this subject, to which the last 500 pages with 217 illustrations is devoted. Dr. Maurice Langeron, director of the section of mycology in Brumpt's laboratory, subsidized by the Rockefeller Foundation, is responsible for many of the new illustrations of fungi from cultures in this laboratory. Of great general interest is the author's opening chapter on a general survey of the wide occurrence, biologic and evolutionary significance, unique adaptations and complicated life cycles of parasites in general in the plant and animal worlds. Special interest in the diverse fields included in this monumental work is derived from the author on details of minor significance in many cases of greater import in others, but all will gladly pay homage to the breadth of learning the skill in presentation and the comprehensiveness of treatment found in its pages. Some of the important results of American work in schistosomiasis, trypano-

asis and amebiasis are omitted, an incorrect biologic analysis of stages in the life cycle of the malarial parasites is made, and the inclusion of the spirochetes among animal parasites instead of the bacteria, where they more properly belong, is unjustified. Their inclusion in the book has, however, a biologic justification, since some of them have arthropod intermediate hosts.

Even a casual inspection of the book should convince any medical faculty of the intricacies and scope of human parasitology. Let us hope that it may lead to a suitable provision in curriculums and clinics for broader and more adequate instruction in this subject in the preparation for the practice of medicine.

School Health Problems. By Laurence B. Chenoweth, A.B., M.D., Professor of Hygiene, University of Cincinnati; and Theodore K. Selkirk, A.B., M.D., Instructor in Pediatrics, College of Medicine, University of Cincinnati. With a chapter on School Health Administration. By Richard Arthur Bolt, M.D., Dr.P.H., Director, Cleveland Child Health Association. Cloth, Price \$3.00. Pp. 387 with 112 illustrations. New York: F. S. Crofts & Co. 1937.

Intended for "students in education, teachers in service, and others interested" the book can be heartily commended to those who will take the time to study and digest it. It is a concise and complete storehouse of the necessary facts to acquaint them with "the broad general nature of health problems in schools." The authors have not dwelt so much on detailed technics as on visualization of the problems and developing a sensible, practical approach to them. The book deals with growth, nutrition as a factor influencing growth, malnutrition, physical examinations of school children, control of communicable diseases, seeing and light, acoustics and hearing, special classes for handicapped children, tuberculosis, mental hygiene, physical education and the accident problem, and health administration. Especially helpful are the extensive lists of references, which appear to be well selected and which should make of this book an excellent starting point and introductory volume for a student entering the school health field anew, as well as a serviceable textbook for those who wish to go no further into the subject than these authors lead. Physicians, including most school physicians, will applaud the authors' conclusions as to who should examine the school child. "Since continuous supervision by a personal physician is desirable, more effort should be made in the school health program to have this as an objective. Unless this is done there may be a tendency to rely too much on the school examinations. Such dependence

is not a desirable objective, first because the examination is limited in scope and second because it is a service that will be withdrawn when the child leaves school. Every effort should be made to have children examined by their own physicians in addition to their examinations at school." Yet the authors warn that "it is a matter of practical importance that such an annual survey is performed only for a very small proportion of the child population" for reasons which include inability to afford it, procrastination and the ancient tendency to see a doctor only for pain or sickness. The book has a good glossary and an excellent index. It is worth the studious attention of all those interested in health problems in education.

Estudos cirurgicos. Por Eurico Branco Ribeiro, cirurgiao da beneficencia portugueza e do Sanatorio Santa Catharina. 2ª serie. Fabrikoid. Pp. 245 with illustrations. Brasil: Sociedade Editora Medica Limitada. 1936.

This series of seventeen essays on various surgical subjects is the second of its kind published by Dr. Ribeiro of the Santa Catharina Hospital, São Paulo, Brazil. The series, based on ten cases observed by the author, opens with a study of "nervous caseation" observed in leprosy. In the neuritis of leprosy the peripheral nerves increase in volume, showing separate bead-like enlargements or perhaps necrosis followed by caseation of coagulation. The different cases are classified according to the particular surgical method of treatment used. An essay on the serum treatment of acute appendicitis describes ten cases in which, according to the author, good results were obtained. Three studies are devoted to the consideration of hypertrophy of the pyloric muscle in adults, which the author thinks should be treated as a pathologic entity distinct from the hypertrophic stenosis of infancy. The clinical, radiologic, surgical and

anatomopathologic aspects of the disorder are discussed, based on a critical study of the author's personal cases. A partial gastroduodenectomy is recommended as the treatment of choice, based on the view that the condition is mainly due to nervous disturbances. From his study of cancer of the gallbladder, the author concludes that in all cases of chronic inflammation of the organ, especially that due to lithiasis, in which ordinary clinical treatment fails, cholecystectomy should be resorted to. There is an excellent clinical study of acute edematous pancreatitis. The author believes that the cause in four fifths of the cases is to be found in a calculous gallbladder and that therefore a simple cholecystectomy should be the treatment of choice. In his study of tetanus the author is of the opinion that the treatment should be schematic, namely, treatment of the tetanic focus, general specific treatment and symptomatic treatment. The specific treatment should be the employment of antitoxic serum by the subcutaneous or intramuscular route.

Le principe antipernicieux de l'estomac. Sa recherche dans le sue gastrique par le test du rat blanc. Par le Docteur Paul Andre Rambert de la Faculté de médecine de Paris. Paper. Pp. 107. Paris: Amédee LeGrand. 1937.

This monograph presents a rather complete review of the work on the relation of the stomach to the production of the anti-pernicious anemia substance. The subject matter is discussed under gastric preparations and their therapeutic effect in pernicious anemia, action of gastric juice, action of stomach extracts, the effect of gastric resection, the physiologic anatomy of the stomach and the anti-pernicious anemia principle. Rambert reports his own experiments on the effect of the injection of gastric juice into rats as a test for the presence of anti-pernicious anemia substance. He also confirms the work of Singer, who first described this procedure. The bibliography of 388 articles is well chosen. The material is presented in an easily readable form and should serve as a convenient summary for investigators working in this field.

National Health Series. 20 volumes consisting of the following titles:

Adolescence by Maurice A. Bigelow, Ph.D., D.Sc.
How to Sleep and Rest Better by Donald A. Laird, Ph.D., Sc.D.
Love and Marriage by T. W. Galloway, Ph.D., Litt.D.
Exercise and Health by Jesse Peirce Williams, A.B., M.D.
Food for Health's Sake by Lucy H. Gillett, B.S., M.A.
Hear Better by Hugh Grant Rowell, M.D.
Cancer by Francis Carter Wood, D.Sc., M.D.
Diabetes by James Ralph Scott, M.D.
The Expectant Mother and Her Baby by R. L. DeNormandie, M.D.
Taking Care of Your Heart by T. Stuart Hart, M.D.
The Healthy Child by Henry L. K. Shaw, M.D.
The Common Cold by W. G. Smilie, M.D.
The Common Health by James A. Tobey, Dr.P.H.
What You Should Know About Eyes by F. Park Lewis, M.D.
Tuberculosis by H. E. Kienle-Schmidt, M.D.
Why the Teeth? by Leroy M. S. Miner, D.M.D., M.D.
Your Mind and You by George K. Pratt, M.D.
Staying Young Beyond Your Years by H. W. Haggard, M.D.
The Human Body by Thurman B. Pice, A.M., M.D.
Veneral Diseases by William F. Snow, A.M., M.D.
Cloth. Per volume 35 cents. New York: Funk & Wagnalls Company. 1937.

These titles constitute a reassue in 1937 of the well known series of small health booklets issued by the National Health Council in 1934. A few of the titles have been replaced with new ones and those which have not been replaced have been brought down to date. The new edition instead of being issued in limp fabrikoid, is in cloth of bright colors. These books represent authentic information in compact form at small cost, though the price is now 5 cents per volume more than the price of the first series. The most significant feature of this health series is its distribution. The books are sold from metal display racks, where their brightly colored bindings attract attention. They can be purchased not only in book stores and department stores but in railroad stations, banks, office building lobbies and other places where large numbers of persons pass by. The series is an interesting example of how health information can be retailed cheaply through the channels of ordinary trade and still be authentic. This series represents probably the most significant service to the cause of public health that has been accomplished by the National Health Council.

On the Incidence of Anæsthetic Complications and Their Relation to Basal Narcosis By C J M Dawkins M.A. M.D. B.Chir., Anaesthetist to the Dental Department Middlesex Hospital London Foreword by Joseph Blomfield O.B.E. M.D. Published for the Middlesex Hospital Press Boards Price 3s 6d Pp 56 London John Murray 1936

This is a careful study of anæsthetic complications, with special emphasis on the effect of preliminary narcotic medication on the incidence of pulmonary complications. Three groups of cases are studied, a series of more than 3,000 cases occurring in the years 1921 to 1925, "prior to the introduction of basal narcosis," a series of more than 3,000 cases occurring in the years 1931 to 1935, "when basal narcosis was well established," and a series of more than 1,500 personal cases. While there is interesting and helpful discussion of all kinds of anæsthetic complications, main interest is always on pulmonary complications and the effect thereon of preliminary narcosis. The crux of the whole matter is contained in the accompanying table.

The number of these cases is sufficiently large to make the figures of value, and the variation in results is sufficiently great to indicate clearly an increased incidence of pulmonary complications when basal narcosis is used. Unfortunately it is not made unquestionably clear just what is meant by "basal narcosis only." The context leads one to believe that this does not refer,

Summary of Pulmonary Complications

	Total Cases	Pulmonary Morbidity Cases		Pulmonary Mortality Cases	
		Number	Per Cent	Number	Per Cent
1921-1925	3 229	221	6.84	28	0.86
1931-1935 { Excluding basal narcosis	2 390	151	5.83	20	0.77
{ Basal narcosis only	500	56	11.09	4	0.79
Personal cases	1 542	33	2.14	8	0.52

as the wording would seem to suggest, to a group of cases in which no anesthesia other than basal narcosis was used, but rather to a group of cases in all of which basal narcosis was given and apparently supplementary anesthesia as well. "Basal narcosis" consisted of preliminary medication sufficient to make the patient definitely drowsy and usually contained some pentobarbital sodium. The patients considered for purposes of comparison had some preliminary medication, usually a small dose of morphine and atropine, but not enough to make them drowsy. In thirteen tables of statistics are data concerning these cases presented in such detail and from so many different angles that any one having any doubts about the conclusions arrived at can resolve them by a study of the material.

Report of the Subcommittee on Health and Disability of the Citizens Committee on Public Welfare (State Medical Society of Wisconsin). Submitted to Governor Philip F. La Follette. Paper. Pp 91. Madison 1937.

This report is based on a study of the state institutions infant and maternal mortality, county nurses, state departments dealing with health, legislative reference library, social security, health aids and medical and dental care of the indigent. It is noted that there has been a continuous reduction of mortality, until Wisconsin has one of the most favorable rankings of any state in the Union or of any important nation. Recommendations are divided into two parts—those dealing with administrative changes and those requiring new legislation. The report is a compact survey of public health and institutional resources in Wisconsin and an outline of recommendations that undoubtedly forecast future developments with considerable accuracy.

Dictionnaire des bactéries pathogènes pour l'homme, les animaux et les plantes. Bactériologie humaine. Dr. Paul Hauduroy et Dr. G. Ehringer. Bactériologie animale. Dr. Ach. Urbain et Dr. G. Guillot. Bactériologie végétale. Dr. J. Magrou. Cloth. Price 140 francs. Pp 597. Paris. Masson & Cie 1937.

The authors of this dictionary of bacteria utilize Bergey's Manual of Determinative Bacteriology as the basis for their nomenclature and classification, though declining to approve this effort of the Society of American Bacteriologists to bring order out of chaos. The principles of Bergey's system, they say, could be more logical, the definitions of certain genera are too vague and of others too narrow, and the genera described as

gram negative contain gram positive species. They call for an international codification of bacterial nomenclature such as has been accomplished in botany and zoology. As a move in this direction they reprint the International Rules of Botanical Nomenclature, adopted by the first Congress of Microbiology in 1930. The dictionary includes an alphabetical list of 650 genera and species of microbes. For each species it gives the synonyms, morphology of cultural forms and spores, the cultural requirements, and the biochemical and biologic properties. A tabular presentation of the distinctive characters in a dichotomous system provides a short cut to the identification of species. Full indexes of the genera and species of host plants and of the genera, species and synonyms of bacteria add to the usefulness of the dictionary. The publishers have done well with the typography, and the authors have arranged the great mass of detail with critical skill and simplicity.

Pathologie und Therapie des peripheren Kreislaufes. III. Oeynhauser Arztvereinskurs 16 und 17. Mai 1936. Herausgegeben vom Arztverein zu Bad Oeynhausen. Boards. Price 7 marks. Pp 136 with 4 illustrations. Dresden & Leipzig. Theodor Steinkopff 1936.

This is a collection of lectures by ten German authorities on circulatory disturbances. The subjects discussed are the anatomy and pathogenesis of disturbances of the arterial tension, the physiology of vasodilator substances, a clinical consideration of hypertensive arterial disease, surgical therapy of hypertension, the role of the veins in the regulation of the circulation, the pharmacology of hypertensive disease, the therapy at spasms and baths, the pathology of hypertensive disease and a summary of present-day therapeutic measures. The lectures are carefully prepared and well worth study by those with especial interest in the problems of abnormal arterial tension. No attempt was made to include any discussion of the literature; the lectures apparently represent the personal views of the writers. Although little that is new or particularly constructive was found, the volume is an excellent summary of present-day German thought. Because the lectures were given at Spa Oeynhausen, there is naturally great emphasis on this type of watering place as a means of therapy.

The Intimate Side of a Woman's Life. By Leona W. Chalmers. Foreword by Winfield Scott Pugh, M.D. Illustrated by Frank H. Netter, M.D. Cloth. Price \$1.50. Pp 128 with 21 illustrations. New York. Pioneer Publications, Inc. 1937.

This small book has been written by a layman primarily for the lay reader. Apparently there was some measure of medical guidance of the author, this being indicated by the fact that Dr. Winfield Scott Pugh has written the foreword, and the illustrations are by Dr. Frank H. Netter. Its main theme seems to be that cleanliness is the secret of feminine charm and the highroad to marital happiness. Vaginal douching, types of syringes, positions for douching, and its technique constitute the main subjects of the text. It is around this and constipation that this booklet has been built, anatomic descriptions, discussion of menstrual pain, leukorrhea and certain details of general body hygiene and exercises are included. Vaginal douching is recommended to an extreme and accorded an importance not concurred in by the majority of gynecologists. The last chapter contains a useful list of "don'ts," and on this account, too, the booklet will be found of some value even though less so than suggested by its broad and inclusive title.

Health Protection of Welders. Paper. Pp 27 with 2 illustrations. New York. Industrial Health Section. Metropolitan Life Insurance Company. [n.d.]

This is one of a series of brochures, appearing at irregular intervals, prepared by the Metropolitan Life Insurance Company and covering some aspect of industrial hygiene or industrial medicine. It is peculiarly characteristic of these publications that they appear just when most needed. The present pamphlet describes the various forms of welding and the hazards associated with each. The most important dangers are electrical shock and burns, radiant energy, gases, fumes and dust. It has long been known that welding, and particularly arc welding, has harmful potentialities growing out of ultraviolet and oil-ray exposures. It has been determined recently that even more significant exposures may result from nitrous gases and the carbon monoxide generated in arc welding. This brochure covers in detail

these exposures, together with the dangers associated with the metal and mineral oxides produced in welding operations. It will be of service to individual workers, labor organizations, employers and physicians.

The Concept of Social Medicine as Presented by Physicians and Other Writers in Germany 1779-1932 By Gertrud Kroeger Dr rer pol Introduction by Michael M Davis Paper Pp 40 Chicago Julius Rosenwald Fund 1937

This study summarizes German material that is little known in this country dealing with public health and generally involving the activities of state or local governments. The tendencies of such activities were greatly influenced by wider social developments. The early work of Virchow, Neumann and their group was closely related to the revolution of 1848. When that revolution failed and the rise of nationalism became a dominant characteristic of the period, von Stern and another group focused much of their attention on state activity in fields closely analogous to what is known as public health in this country. When health insurance was established in Germany by Bismarck in 1883, a group headed by Alfred Grotjahn turned its attention to the possibilities of health care through a synthesis of public health insurance and what it designated as "social pathology" and "social therapy" and sought to utilize the conclusions of the social sciences in connection with medical care.

Globe Trotting with a Surgeon By Alexander H Peacock M.D. Cloth Price \$2.50 Pp 276 with photographs by the author Seattle Washington Press of Lowman & Hannford Company 1936

Every traveler feels himself an explorer. It is hard for any of us to realize, however, as we move around the world that with modern types of transportation great numbers of people are now getting about into places which formerly were limited to an exceedingly few. Dr Peacock has seen the world for himself and he has embellished his descriptions with excellent photographs of his own making. As each of us reads in the writings of others descriptions of what we ourselves have seen, our own memories come to light and our enjoyment is multiplied. Any one who has followed the paths traced by Dr Peacock will find that his book will yield them enjoyable hours freighted with memories and reminiscences.

The Diagnostics of Pain. Lectures for Medical Students and Physicians Held at the University of Copenhagen in the Autumn of 1934 By Th B Wernke Paper Pp 116 with 23 illustrations London Oxford University Press Copenhagen Levin & Munksgaard 1936

This little book contains a series of lectures which were given at the University of Copenhagen in the autumn of 1934 for medical students and physicians. No sharp distinction of subjects separates the seven chapters contained in the book. The translation from the Danish leaves much to be desired, since the sentences are frequently long and involved. All forms of pain, the author states may be most conveniently divided into three main groups: (1) direct pains localized to the site of irritation; (2) indirect pains localized at some distance from the site of irritation; and (3) combined pains consisting simultaneously of direct and indirect pains. These lectures are concluded with the information that a larger later work is intended, which will divide all pains occurring in man into eight groups.

Experimental Physiology By George H Bell M.B. B.Sc. M.D. Lecturer in Physiology University of Glasgow Boards Price 4s 6d 1 p 70 with illustrations Glasgow John Smith & Son Ltd 1937

As stated in the preface, this is a laboratory manual especially designed for the particular circumstances at the University of Glasgow, therefore the book offers little attraction for those working under other conditions. Only sixteen laboratory periods are offered, the first six and a part of the seventh are experiments on the frog. Approximately the same amount of time is devoted to experiments on special senses on human subjects. The remainder of the time is devoted to laboratory experiments on circulation and respiration and to observations on human subjects. All the experimental procedures are the conventional ones, such as are found in any laboratory manual. No attention is given to digestion, metabolism, endocrines, kidney, or the lymphatic system.

Pharmacopœia and Guide School of Tropical Medicine and Carmichael Hospital for Tropical Diseases Calcutta Fabrioid Price Rs 2/8 Pp 153 Calcutta School of Tropical Medicine 1936

This is a small handbook of convenient size, neatly bound and similar in content to some of the hospital formularies that are used in this country. It is intended primarily for use of postgraduate students who are unfamiliar with the armamentarium used in the treatment of tropical diseases. It contains the usual formulas for preparations, posologic tables and discussions of the treatment of many conditions, but principally those peculiar to the tropics. Its usefulness outside the tropics is limited more or less to that of a reference volume for the treatment of the occasional case of tropical diseases seen elsewhere. It contains tables of weights and measures, dilutions, strengths of solutions and food values, and blank pages for taking notes.

British Health Resorts Spa Seaside Inland Including Those of Australia Canada Cyprus New Zealand South Africa and the British West Indies. An Appreciation of Their Medical Values and Uses in the Prevention and Cure of Disease Edited for the Association by R Forrescue For M.D. F.R.C.P. F.R.Met.S. Hon Member of the American Climatological and Clinical Society. With a foreword by The Rt Hon Sir Kingsley Wood Minister of Health. Official Handbook of the British Health Resorts Association Paper Price 2s 6d Pp 288 with illustrations London J & A Churchill Ltd 1937

This official handbook of the British Health Resorts Association is intended as a catalogue for those desiring specific information on the climatic conditions of British health resorts. In addition to the resorts in England, Wales and Scotland some spas and resorts in Australia, Canada, New Zealand and other British commonwealths are briefly described.

Experimental and Clinical Studies of the Spine of the Dog By Geoffrey Bernard Brook D.Sc. F.R.C.V.S. Cloth Price \$2 Pp 122 with 50 illustrations Baltimore William Wood & Co 1936

The first part of the book deals with anatomic investigations of the atlanto occipital space in its relation to the puncture of the cisterna magna. It is found that the depth of the cisterna at the foramen magnum is 0.5 cm in large dogs and 0.3 cm in small dogs. The average amount of cerebrospinal fluid obtained was 5 cc. The white cell count increased with repetition of punctures. The second part of the book deals with the effects of an iodized oil containing 0.54 Gm of iodine per cubic centimeter. It is a radiopaque medium which is easily tolerated by the dog and which may be used to show the location of a spinal block. It was observed that after injection in the cisterna magna it took about 110 minutes for it to descend into the subarachnoid culdesac.

The Metabolism of Living Tissues By Eric Holmes M.A. M.D. Fellow and Tutor of Downing College and University Cambridge Cloth Price \$2.25 Pp 235 New York Macmillan Company Cambridge University Press 1937

It is impossible in any short review to give an adequate conception of the rich material in this monograph or of the clear, simple method of presentation. In general, the work deals with the more intricate aspects of the physicochemistry of living tissues. It is a simplified analysis of the significant relations between chemical structure and physiologic action. The chapter headings include such subjects as enzymes, oxidations, liver in relation to protein, fat and carbohydrate, kidney, muscle, nerve, endocrines and vitamins. There is also considerable discussion of the importance of electrolytes. It is a remarkable accomplishment that so much sound, scientific discussion is crammed passed within such small space. Unfortunately there is no bibliography.

Medical Diagnosis. Some Clinical Aspects By S Levy Simpson M.A. M.D. M.R.C.P. Physician to Wilkesden General Hospital. Cloth Price 10s 6d Pp 244 London H K Lewis & Co Ltd 1937

Seven volumes of the General Practice Series had been released and four were in preparation at the time of publication of this volume. All diagnosis is acquired as stated in the preface "at the bedside by careful and minute observation of the living patient. The diagnostic criteria listed are of necessity brief and exceedingly incomplete. Nevertheless the beginning medical student and possibly the practitioner who has unusually limited time at his disposal may find some use for these brief discussions."

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Injunction to Restrain Unlicensed Practice, Violation by Subterfuge—Norman G. Baker, a layman, owned and operated the Baker Hospital at Muscatine, Iowa, for the treatment of cancer and certain other diseases. In *State v. Baker* (Iowa), 235 N. W. 313 (abstr. THE JOURNAL, Jan 9, 1932, p. 168) the Supreme Court of Iowa held that Baker was practicing medicine and enjoined him from "directly or indirectly, either by himself or by his agents, from engaging in the practice of medicine and surgery within the state of Iowa without having a license to so do." The events following the issuance of that injunction are not stated in the instant opinion. Apparently, however, Baker "leased" the hospital or gave possession of it under a contract of sale to certain individuals. The terms and conditions of the lease or contract are not stated. Subsequently, contempt proceedings were instituted in the Supreme Court of Iowa against Baker alleging that he had violated the injunction. The matter was referred to the district court judge in Muscatine, who after an extensive hearing reported to the Supreme Court that in his opinion Baker had violated the injunction by engaging in the practice of medicine since the issuance of the writ. The testimony adduced at the hearing tended to show that Baker and those who operated the Baker Hospital under his direction under the guise of a formal lease or contract of sale were, in fact, all engaged in a common scheme and design to perpetrate a fraud on the court and that the lessees were, in reality, the employees of Baker or the Baker Investment Company, of which he was the manager and, in fact, the real owner. Baker contended that if the medical practice act of Iowa is construed as forbidding the owner of a hospital from employing licensed physicians to practice medicine and attend patients therein, the act would be violative of the fourteenth amendment to the federal constitution. But, said the court, it has uniformly been held that reasonable regulations are permissible under the police power of the state as to occupations affecting public health and welfare.

From a consideration of the entire record, the Supreme Court thought there was no way that the evidence could be reconciled on any reasonable or rational basis except that Baker and his accomplices and confederates in the operation of the Baker Hospital were engaged in perpetrating a stupendous fraud against the court and that the leases and contracts were but a cunning subterfuge. The court refused to shut its eyes to such transparent trickery and said that a court so supine as to overlook such conduct would merit the contempt of all fair-minded men.

Baker was consequently held guilty of contempt of court—*State v. Baker* (Iowa), 270 N. W. 359.

Health Insurance Reasonableness of Demand That Disabled Insured Submit to Tests of Blood and Spinal Fluid—The defendant insurance company promised to pay Henning the plaintiff, certain benefits if he became disabled as a result of accident or of sickness other than a venereal disease. The plaintiff brought suits against the insurance company to recover benefits for disability due to a "paralytic condition." The defendant company brought a cross-action to enjoin the plaintiff from instituting another suit on the policies of insurance held by him and to require him to submit to a physical examination. From a judgment against it in each of these actions, the defendant company appealed to the Court of Appeals of Kentucky.

Each of the insurance policies issued to the plaintiff provided that "the company at all times shall have the right and opportunity to have its own medical examiner examine the person of the insured when and so often as it may reasonably require during the pendency of any claim for weekly indemnity." Section 673 of the Kentucky statutes contained a similar provision but provided further that no action at law or in equity may be maintained in any court of the state for the recovery

of any claim for benefits when an examination of the person of the insured by the insurance company's physician has been either obstructed or refused. The insurance company pointed out that under its policies it was not liable to the plaintiff for the payment of any benefits if his "paralytic condition" was the result of syphilis, a venereal disease, and that a Wassermann test of his blood and an analysis of his spinal fluid were reasonably necessary to ascertain whether or not the plaintiff's condition was the result of syphilis. The company introduced evidence that the plaintiff had submitted to an examination by the insurance company's physicians but had refused to allow them to draw either blood or spinal fluid for the purposes of performing these necessary tests.

The insurance company, said the Court of Appeals, had a right under either the provisions of its policies or of the state statute, or under both, to demand that the plaintiff submit himself to a scientific test of his blood or of his spinal fluid, or of both. Whether the plaintiff's disability resulted from a venereal disease could not be determined otherwise than by the tests proposed. The Court of Appeals therefore held that, if the plaintiff declined to submit to such tests, then the trial court should dismiss his suit in accordance with the state statute. On the other hand, if the plaintiff submitted to such tests and the examining physician determined that his disability was caused by venereal disease, then the case should be tried under the evidence.

Accordingly, the Court of Appeals reversed the judgment of the lower court that denied the insurer's request that the plaintiff submit to a physical examination, but it affirmed the judgment of the lower court that denied the injunctive relief sought by the insurer to prevent the plaintiff from instituting another action on his policies—*American Life & Accident Ins. Co. v. Henning* (Ky.), 97 S. W. 2d 798.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Epidural Infections.—Browder and Meyers describe seven cases of spinal epidural infection. Five belong to the group designated as spinal epidural abscess representing the relatively acute process and two belong to the group designated as spinal epidural granuloma, representing the more chronic process. Five patients died and two are living at present. The clinical picture is fairly constant and for the more acute forms at least, constitutes a fairly definite syndrome, consisting of a history of a previous infection, boring pain in the spine, radicular pain and finally involvement of the spinal cord. In the chronic cases there is less definition of the syndrome although the features outlined are often represented if an adequate history is obtainable. A consideration of the pathogenesis of the disease reveals two main modes by which the spinal epidural space may be invaded in the first, by direct extension from an infection adjacent to the vertebral column in the second, by a hematogenous route from a more remotely situated focus of infection. The authors propose reasons for believing that cases of this kind are characterized by a zone of metastatic vertebral osteomyelitis which infection subsequently spreads into the spinal epidural space.

Treatment of Anal Fissure.—Weiss believes that the treatment of anal fissure is feasible by injections of local anesthetics in oil and can be accomplished in the ambulatory patient. Assuming that the fissure is situated at the posterior commissure, the patient is placed either in the lithotomy or in the Sims position. A 1½ inch 22 gage needle is inserted through the normal skin from 0.5 to 1 cm distal to the fissure edge, and 1 mm of a solution (0.5 per cent of nupercaine, 1 per cent of phenol, 10 per cent of benzyl alcohol and 88.5 per cent of sweet almond oil or 0.2 per cent of eucalypti, 3 per cent of ethylammonioacetate 5 per cent of benzyl alcohol and enough sweet almond oil to make 100 per cent) is injected immediately. This will allow the introduction of the left index finger through the anal orifice and thus enable one to feel the needle, guiding it as it is advanced in the subcutaneous tissue to a place just beyond the apex of the fissure, but at no time to penetrate the bed of the fissure or mucous membrane. From 0.5 to 1 cc of the selected solution depending on the size of the lesion is then injected, beginning at the point beneath the fissure apex and continuing as the needle is being drawn out. The needle is then partially withdrawn and with the index finger still in the anus it is redirected being guided into the sphincter muscle first on one side adjoining the fissure where 1 cc is deposited, and then on the other side adjoining the fissure. It may take from one to four or five treatments until complete repair of the fissure is accomplished. The important fact is that after the first treatment the patient has immediate relief, gains confidence, and bowel movements are characterized by the absence of ensuing pain, smarting or soreness. If a sentinel pile is

present, its removal is essential for cure. This may be done after the first injection or at a date in the near future. No additional infiltration of a local anesthetic is required for its ablation. The use of one of the solutions extends the period of anesthesia and eases the spasm of the anal sphincter over a sufficient time to allow healing. Of the thirty patients treated with these formulas, two developed sloughs, three patients seen after six months complained of an occasional itching sensation which was slight and not constant but examination revealed no break in the mucous membrane, and the others have had no recurrences.

Infections of the Face.—Maes reviews the twenty fatal cases of infections of the 'dangerous area' (the triangle from the angles of the mouth to the bridge of the nose) of the face that were observed in two hospitals during nine and six years, respectively. The area is dangerous for anatomic and physiologic reasons. The reasons include the thinness of the skin, its constant exposure to trauma, its rich vascular supply, which provides a direct pathway from the surface to the interior of the cranium, the predominance in this area of connective tissue, which adapts itself poorly to infection, and the constant motion of the lips, which militates against any localization of infection. More important than any of these anatomic and physiologic reasons is the factor of trauma, which is present in 90 per cent of all cases and is introduced by the patient or his physician or both. The infecting agent is usually the staphylococcus and the spread is by way of the subcutaneous plexus and the angular and ophthalmic veins. The condition begins as a carbuncle or simple boil. When the factor of trauma is introduced, stagnant blood is provided as a rich culture medium for bacteria, the integrity of the protective leukocytic wall is destroyed, the infection spreads rapidly by way of the rich vascular supply, and the steps of the pathologic process include thrombophlebitis, thrombosis of the cavernous sinus, massive blood stream infection, meningitis and metastatic abscesses. The disease begins with a mild local discomfort, followed shortly by extensive swelling, edema and induration of the adjacent tissues. The symptoms and signs after this stage include severe pain, chills, hyperpyrexia, delirium or coma and prompt death. All types of local and intravenous therapy have been advised, but the general opinion now is that conservative measures chiefly absolute rest of the parts, warm compresses and supportive measures, give the best results while surgical incision gives the worst. Ligation of the angular vein is theoretically correct, but of little practical value, and a few successful operations have been reported for drainage of the affected cavernous sinuses.

Cullen's Sign in Acute Pancreatitis.—Fallis believes that the extreme rarity of Cullen's sign suggests an anatomic variation of the structures at the umbilicus. Abnormal apertures in the peritoneum and transverse fascia would allow extravasation of blood from the peritoneal cavity to the subcutaneous tissues. Another explanation is that the blood travels extraperitoneally. This hypothesis is all the more plausible when

it is recalled that the pancreas is essentially an extraperitoneal organ, lying as it does behind the peritoneum and being covered by peritoneum only on its anterior surface. Effusions of blood resulting from disintegration of the gland could conceivably track around in the subperitoneal space between the peritoneum and the transverse fascia and, reaching the midline anteriorly, would be limited by the suspensory ligament of the liver above and the urachus below the umbilicus. Collections of fluid would then tend to gravitate along these structures and pool in the potential subumbilical space, where there is direct contact with the subcutaneous tissues owing to the absence of the transverse fascia in this region. Diffusion of excess fluid into the flank would readily occur from here. The author offers in confirmation of this postulate the observation that in two of his cases there was no blood-stained peritoneal fluid found at operation and yet a positive Cullen sign was present, while in two other cases of acute pancreatitis under consideration at the same time there was found at operation, in both instances, a large amount of blood stained peritoneal fluid but no discoloration around the umbilicus. The theory of extraperitoneal spread is also applicable to cases of ruptured ectopic gestation and may explain the rarity of the sign. On this basis, however, the sign would be positive only in those cases in which the extraperitoneal portion of the tube was involved in the rupture and extravasation took place between the layers of the broad ligament. In a series of thirty-five patients operated on for acute pancreatitis in the author's hospital, a positive diagnosis was made in only five instances and one of these patients had suffered from a previous attack of acute pancreatitis. The diagnostic value of a positive Cullen sign is emphasized by pointing out that of the remaining four cases in which a correct preoperative diagnosis was made three were made on a basis of a positive Cullen sign. A good light is essential for the recognition of the sign.

Liver Deaths.—"Liver deaths," as has been noted occur most frequently in diseases of the biliary tract in which the liver usually shows some pathologic changes at the time of operation. But hepatic damage may be present in other cases due to infection, intestinal intoxication or, DeCourcy thinks, anemia. If it is present, even to a slight degree, any laparotomy may cause physical, chemical infectious, mechanical and toxic traumas (Hejdy) sufficient to produce severe toxemia when liver function is impaired. In the two cases that the author cites the only common factor was a considerable degree of prolonged anemia resulting from preoperative loss of blood. The diminished or poor blood supply to the liver resulting from anemia may be the cause of preoperative damage to the liver cells or of some diminution of the liver function. It has been shown both experimentally and clinically that building up the glycogen reserves of the liver protects it from damage and increases its detoxifying action. Since his experience leads the author to believe that anemia may be a factor in the causation of liver damage, he recommends that dextrose be given preoperatively, as an adjunct to transfusion, to all patients who show any evidence of anemia.

Time Factor in Irradiation of Malignant Tumors.—Melnick and Bachem find that following irradiation sensitive tumor cells undergo primary degenerative changes which are of the nature of simple necrosis. Refractory tumor cells

become altered in their chromosomal structure by irradiation; an alteration which results in the development of abnormal forms (giant cells, in the tumors described). These abnormal forms developing as a result of the action of the rays on the nuclei fail to survive. They degenerate in a specific manner (calcification of the nuclei). The effect of small divided doses of radiation is fully cumulative in producing changes in the chromosomes and genes of refractory cells. Because of this full cumulative effect on their nuclei, divided dose methods offer the possibility of destroying a tumor by transforming its cells into abnormal forms, when the lethal massive dose to the tumor is injurious to the host. Protracting the individual divided dose is probably of no value. In the authors' experiments no significant gross or microscopic differences in effects were found between the fractional and the protracted fractional treatments. Fast growing tumors may increase in size to a dangerous extent before the effect of divided doses becomes manifest. For such tumors the saturation technique is a logical choice. An initial moderate massive dose destroys the sensitive cells. Subsequent divided doses destroy the refractory cells by the mechanism of altering their hereditary structure. In the experiments reported, such a saturation method was found to be most efficient.

Severe Burns and Skin Grafting.—Padgett discusses a series of 144 burned persons. In the care of the severely burned, greater emphasis should be focused early on alleviation of the profound systemic disturbance than is placed on the care of the local lesion. The recognition of the depth and the area of complete epithelial destruction is an essential point to be grasped if one is to understand the principles of resurfacing and the basic cause of contractural deformity. Early resurfacing after a large complete loss of skin should be the goal of the surgeon, because of the prevention of contracture with the functional incapacitation that accompanies them. Provided the general condition of the patient is good, success in growing thin skin grafts on a granulating area

is directly proportional to the general cleanliness of the surface. In an anemic person the chance of a good take on a surface of granulation tissue is decreased. In the successful grafting of skin, dependence on simple fundamental principles and methods, in contradistinction to a special type of graft with or without a "far fetched" method of placement or puncturing or dressing, is important. In the correction of cicatricial defects after complete healing has occurred, the decision whether to use a thin graft or a full thickness graft depends on a careful balancing of the characteristics of the two grafts, the main object to be attained in a given region and the relative risk of failure to get a good take. Sometimes the disability entailed in the removal of the graft and the length of the period of postoperative dressing also become factors to be considered. Isodermal grafting is not a practical procedure unless an identical twin is available.

Concealed Hemorrhage and Traumatic Shock—Harkins and Roome point out that in all cases of wounds and trauma there is some swelling. Hemorrhage occurs in some and only edema in others. They present cases that illustrate the importance of quantitative studies of the amount of swelling after trauma. The fluid present in these swellings contains a higher percentage of proteins than ordinary edema fluid and hence its loss may lead to circulatory disturbance. The cases cited are of concealed hemorrhage and extravasation of plasma into tissue space. The resultant swelling is usually greater when measured quantitatively than casual physical examination would have led one to believe. The extensive concealed hemorrhage and plasma extravasation in clinical cases substantiates the experimental observations of others that such local loss of fluid from the circulating blood stream is a factor of importance in the production of secondary surgical or traumatic shock.

Postoperative Headache—The relation of hypertonicity to the development of postoperative headache has never been demonstrated. The experiments with saline solution and water as solvents for procaine hydrochloride have failed to yield any significant information and Koster and his colleagues concede that from the data it cannot be concluded that postoperative headache depends on the hypertonicity or the hypotonicity of the injected solution. No reliable data concerning the effect of varying the pH on the development of postoperative headache are available. After the injection of procaine hydrochloride dissolved in distilled water, headache was not uniformly produced. However, that is not surprising when it is remembered that only 4 cc of the procaine hydrochloride solution is injected into a fluid the minimal amount of which is at least 50 cc and which contains considerable buffer substance. If the one patient who had a headache preoperatively is left out of consideration, there were five patients with postoperative headache among the 100 who were used in the experiments. There was an interval between the experiments on two groups, during which time 135 persons were anesthetized with procaine hydrochloride dissolved in cerebrospinal fluid. Of this number, not a single person had a postoperative headache. Buffer substances are present in cerebrospinal fluid in sufficient quantities to render innocuous ordinary solutions used to develop anesthesia, which might have a pH as low as 5.63.

Black Widow Spider Bite—Ginsburg points out that since the last (1935) report of Frawley and himself there have been treated at the General Hospital of Fresno County forty four

additional cases of black widow spider poisoning. In all, ninety-six cases have been treated. There were no fatalities, and none of the last forty-four patients were even critically ill. A routine treatment is used, which consists of 1 grain (0.065 Gm) of morphine sulfate hypodermically, 20 cc of 10 per cent magnesium sulfate solution given intravenously, to be repeated if necessary, fluids freely, 3 grains (0.2 Gm) of sodium amylal for restlessness, absolute bed rest for twenty-four hours and 10 per cent dextrose intravenously if the patient's condition demands it. The average length of stay in the hospital was 37.3 hours. In the majority of cases, within three to five hours after the use of morphine and magnesium sulfate, the patients had marked relief. When the patients were discharged all symptoms had disappeared except in eight, who had slight tingling and aches in the lower extremities, which persisted from one to seven days. It is believed that the venom or toxin injected by the black widow spider travels very rapidly and that the acuteness of the case depends on the amount and area injected. Acute symptoms set in within one-half to two hours after biting, and the effects appear self limiting. The toxic effect of the bite can be controlled by the foregoing medication.

Crisis in Addison's Disease Simulating Coronary Thrombosis—Sacks reports a case of Addison's disease, which clinically and electrocardiographically simulated coronary thrombosis. The total duration of symptoms was one week. There was no increasing period of weakness as the patient was ambulatory to within a few hours of his death. The most significant abnormalities consisted of large T waves, a large Q_2 and elevation of the RT segments in leads 2 and 3. Coronary sclerosis was present at postmortem examination, and most probably these changes were responsible for the abnormalities described. The rapid fall of pressure with a lowered coronary circulation theoretically may account for some of these changes. The contention of animal experimenters that the cortex of the adrenal is vital to life is substantiated, and the failure of the medullary hormone epinephrine to bring about a remission is well demonstrated. The use and availability of cortical products is vital in the treatment of Addison's disease. Pigmentary changes are of great diagnostic importance but may not have time to develop during the crises of this disease. The absence of these changes increased the difficulties of arriving at a proper diagnosis in the author's case. No accurate calculation for potassium content was possible but it is probable that the patient had an increase of potassium salts in his diet for anemia, as foods rich in iron are rich in potassium, and this proved to be the trigger mechanism that precipitated the fulminating picture.

Creatine and Creatinine Excretion in Infancy—Catherwood and Stearns summarize the data from approximately 500 studies of creatine and creatinine excretion of infants from birth to 1 year of age. The quantities of both creatine and creatinine excreted increased throughout the entire period. The creatine excretion is far more variable than that of creatinine. It is concluded that the creatinine excretion of infants is dependent almost entirely on the quantity of musculature. Infants fed high protein diets have a somewhat higher percentage of the body weight as muscle than infants fed human milk. No consistent relationship was observed between the quantity of creatine excretion and creatine intake, or between creatine excretion and any phase of nitrogen metabolism. The data have been interpreted as indicating that thyroid activity may be directly or indirectly the principal factor concerned in determining the quantity of creatine excretion of infants. During early infancy, creatine and creatinine excretions neither parallel each other nor show any reciprocal relationship; this is considered evidence that the two substances represent different phases of muscle metabolism not closely interrelated.

Poliencephalomyelitis Due to Botulism—Schwarz gives the trend in the development of knowledge of the pathogenesis of botulism that he gathered from a review of the literature. It appears that the pathologicophysiology and pathologic-anatomic features of botulinus intoxication are somewhat unsettled. Because of this he reports the case history and the neuropathologic study of a case of poliencephalitis following botulism in an effort to add further data and possibly throw some light on the latter phase of the problem. The etiologic factor was not definitely ascertained in the case. The clinical syndrome of botulism was so clear, however, that the diagnosis was made on the signs, symptoms and course of the illness. The neuropathology of this fatal case of botulinus intoxication corresponded well with the changes of the original classic cases, both experimental and human. Definite pathologic changes were found in the anterior horn cells of the spinal cord and in the neurons of the cranial motor nerve nuclei. The histologic

modifications were fairly similar to those described previously by other observers. There were edematous changes that were limited chiefly to the agranular cortical area and to the small and middle sized pyramidal cells of the third lamina. Reduction in the number of small cell elements in the nucleus ruber was observed. Although a careful search was made, no bacterial elements were noted in the vacuoles or in their vicinity. It is the author's opinion that the vacuolization in his case was due to edema. The pathologic changes observed differed from those described in the classic cases in that the cells of the oculomotor nerve nuclei showed only slight modifications. No particular changes were noted in the median nuclei of the oculomotor nerve nuclei, as so many other observers have. There were no gross or microscopic thromboses. The vascular endothelium did not show the changes so frequently attributed to it in this condition by a certain group of observers. Perivascular hemorrhages were infrequent and minor. The neuroglia showed no signs of proliferation. They were, however, often very swollen and edematous. In short, the pathologic changes seemed to be of a general and marked edema without demonstrable damage to the walls of the vascular system. Intracellular and extracellular edema were the main features in the cortex. Although some of the cells in the rest of the nervous system presented perineuronal edema, only a few showed even moderate intracellular edema. The motor nerve cells of most of the cranial nerve nuclei showed chromatolytic changes. Yet this was never noted in the anterior horn cells of the spinal cord. And the motor cells of the spinal cord claimed the distinction of possessing the only fat vacuoles seen in any of the cells of the nervous system. Along with the sensory system, the large motor, Betz cells of the prerolentic cortex were unchanged. The geographic distribution of the pathologic changes in the central nervous system corresponded rather well to that of the clinical features of the illness. The changes in the oculomotor nerve nuclei were rather minor when compared to the severity of the clinical involvement of this nerve. The abducens nerve was involved centrally. It does not seem to the author that the pathologic changes observed in the cells of the central nervous system explain the clinical manifestations of the disease in the case. He feels that there is some other factor operative here that produced the severe neuromuscular phenomena. This is probably the peripheral blocking action of the toxin as described by Schubel, Dickson and others.

Progress in Management of Urinary Calculi—Barney and Sulkowitch discuss the management of urinary lithiasis, that is, the removal of a stone in an individual who already has one, and the prevention of recurrence in a patient who has had a stone removed. The subheadings of their discussion include etiology, chemical classification of stones with reference to etiology, classification of conditions leading to phosphate stones, mixed phosphate and other stones, medical aspects of treatment (fluid intake), phosphate stones (hyperparathyroidism).

ism), other phosphate stones (acid regimen), dangers of acid regimen (impaired kidney function), diagnosis, urinary infections and surgical treatment. The intensive and intelligent study of urinary calculi today involves the cooperation of the internist, the clinical chemist and the bacteriologist. It involves a knowledge not only of scientific dietetics but also of endocrinology. The urologist and the radiologist must necessarily depend to a very large and increasing degree on the collaboration of the chemist, the internist and the bacteriologist.

Transvesical Alcoholic Injection for Elusive Ulcer of Bladder—In the treatment of seven cases of Hunner ulcer, Folsom and O'Brien injected absolute alcohol into and about the ulcers. Gas anesthesia was used for all the patients. The injections were made with a long flexible needle through the McCarthy panendoscope. From 2 to 6 cc was injected, 0.2 cc being introduced at each puncture. These were distributed about and directly into the ulcer. After the treatment patients usually spent from sixteen to twenty-four hours in bed and were then able to resume their regular activities. Definite conclusions are not yet warranted, but the authors are impressed by the prompt relief the patients have received and it is their opinion that this immediate relief can be expected in the great majority of cases. The duration of the period of relief is uncertain but with added experience the injections should become more complete, thereby increasing the length of this period. There was no evidence of damage to the wall of the bladder from the alcohol. With care to prevent rupture of the bladder from overdistention, it would seem that the procedure is entirely free from danger.

Ligation of Internal Jugular Vein in Lateral Sinus Thrombosis—Novick maintains that in a given case of lateral sinus thrombosis established definitely, one should not act hastily. With very few exceptions, this is not an emergency in which one has to rush in and ligate the jugular vein imme-

diately. The patient should be carefully observed and treated medically as long as his condition permits and just as soon as the surgeon feels that more radical measures are essential he should reopen the mastoid wound or do a mastoidectomy if this has not been done, then the sinus should be packed above and below, incised and tested for bleeding from each end. If there is bleeding from both ends and the blood is coming from the sinus itself and not from its tributaries it may be assumed that there is no thrombosis in any part of the sinus or the jugular vein. The sinus should be packed and the mastoid incision dressed. If, however, there is bleeding from below and none from above, there is a thrombus somewhere between the upper plug and the torcular herophili. The thrombus should be looked for and removed, if possible the sinus packed and the mastoid wound dressed. Ligation of the internal jugular vein in this instance will be of no further help, since in this area there are many other pathways by which it is possible for the infection to gain entrance to the systemic circulation. On the other hand, if bleeding is obtained from above which means that a thrombus is in all probability present either in the bulb or in the vein itself, ligation of the internal jugular vein followed by the removal of the clot, is justified and should be done.

Liver Function in Hyperthyroidism—Bartels and Perkin performed estimations of the liver function on sixty-six patients with hyperthyroidism according to the method of Quick. Determinations were made on each patient on the day of admission, on the day prior to operation (from eight to fourteen days were taken for preoperative treatment) and on the sixth or seventh day after operation. Twenty-five of the patients suffered from primary hyperthyroidism, which was treated by one stage operation; twenty-five required a two stage operation and sixteen had an adenomatous goiter with hyperthyroidism which required a one stage operation. The test revealed impairment of liver function in cases of hyperthyroidism frequently enough to be of importance as an observation. If in the serial determinations on the twenty-five cases of primary hyperthyroidism the 28 Gm of hippuric acid is taken as the lower limit of normal for the excretion of hippuric acid, it will be noted that on admission only seven patients had normal values. The average hippuric acid excretion for the group on admission was 2.39 Gm. Following preoperative

treatment an increase in the hippuric acid excretion to 266 Gm occurred. From six to seven days postoperatively, an average decrease took place in six of the eight patients in whom liver function was normal before operation. In nine of the fourteen in whom determinations of liver function were made after preoperative treatment and after operation, there was an average decrease in the excretion of hippuric acid of 0.66 Gm. This downward trend after operation is suggestive of the possible strain of operative procedures on the liver function. In the twenty-five cases of hyperthyroidism in which two-stage operations were performed, the average hippuric acid excretion on admission was 176 Gm. From eight to ten days, and in some instances fourteen days, elapsed during preparation of this group of patients for operation. In none of these cases was there evidence of heart failure which might have caused congestion of the liver and thereby produced an alteration of the test. The average amount of hippuric acid excreted during preoperative preparation was found to increase by from 0.48 to 2.24 Gm. In five of twenty-two cases in which tests were carried out after preoperative treatment a normal excretion was noted. This improvement compares favorably with that demonstrated in the group in which one stage operations were performed during the same period. Postoperatively a slight and almost insignificant decrease in the average determination occurred. When the patients returned for the second-stage operation, 20 per cent excreted a normal quantity of hippuric acid, the average quantity being 2.35 Gm. From six to seven days after the second operation an increase in the average excretion occurred in that the tests were normal in 43 per cent of the cases. The average amount of hippuric acid excreted on admission in the sixteen cases of adenomatous goiter with hyperthyroidism was 2.1 Gm. In three cases excretion was normal. After the usual preoperative care the average quantity of hippuric acid excreted increased only 0.11 Gm. But in two of the thirteen cases tested results were normal at this time. There was only a slight increase in the excretion from the time of admission to dismissal. There appears to be a definite relation between the amount of hippuric acid excreted and the level of the basal metabolic rate. In those cases in which the basal metabolic rate was high, the excretion was decreased proportionately. In the cases in which the metabolic rates were only slightly elevated, the excretion was only slightly reduced. The close correlation that was observed between liver function, as indicated by the excretion of hippuric acid, and the value for blood cholesterol gives justification for placing some confidence in the reliability of the hippuric acid test of liver function.

Inhalation Therapy in Cardiac and Respiratory Disease—Barach thinks that the purpose of inhalational therapy may be stated in general as the relief of dyspnea, dyspnea being viewed both as a subjective sensation and an objective pathologic process. The primary objective of this type of treatment must be mainly thought of as an attempt to provide an adequate tension of oxygen in the tissues and to remove the carbon dioxide formed in them as the result of oxidation. The objective pathologic process of labored breathing is closely dependent on chemical factors involved in gas exchange. A prompt diminution of both the volume of the pulmonary ventilation and the effort employed in breathing take place in patients with congestive heart failure after inhalation of high oxygen atmospheres. Therefore there is a significant relation between the chemical factors that are operating and the cause of dyspnea. The interpretation of cardiac dyspnea on the basis of disturbed proprioceptive pulmonary reflexes limits itself simply to an

explanation of the sensation and does not aid a therapeutic physiologic recognition of cardiac dyspnea. As the result of the use of helium, at times with oxygen concentrations which are less than those in the atmosphere, the relief of dyspnea has been shown to be due to a decreased effort in providing an accustomed velocity of gas flow through the respiratory tubel system. It would therefore appear that the organism demands for its psychic comfort the preservation of an equilibrium which has to do with the speed of pulmonary ventilation independent of gaseous exchange. The preventive and therapeutic action of positive pressure respiration in acute edema, in man and in animals, illustrates again the importance of mechanical or physical factors in the physiology of respiration. It seems probable that the therapeutic use of positive pressure will be of value not only in the treatment of pulmonary edema but also in certain related conditions characterized by pulmonary congestion, and it seems also altogether likely that nonarterial pulmonary hemorrhage may be controlled in some instances. Inhalational therapy has gone within the past two decades from a more or less uncontrolled haphazard administration of oxygen employed generally as a measure of last resort to a specialty of medicine which has as its purpose the management of functional disturbances in respiration. The future of this branch of medicine depends on the recognition that the pathologic physiology of clinical disorders in breathing should be given the fullest study in the individual case. The practice of relegating oxygen therapy to technicians or to nurses tends to defeat this aim.

Clinical Giardiasis—Goss reports twenty seven cases of *Giardia intestinalis* infestation discovered in routine stool examinations on 300 private patients, in most of whom examination of the feces was indicated for some other obvious reason. In none of these cases was an attempt made to recover the parasites by duodenal drainage. Practically all of them were fresh stool examinations made after catharsis, with the patient appearing at the laboratory to void the stools. From one to four stools have been examined usually on one day only. These twenty seven cases were compared with 200 cases taken at random, consisting of the same class of patient, on whom routine stool examinations were done. Duodenal ulcer had an incidence more than three times as great in giardiasis as in the control. Biliary disease had no increased incidence in giardiasis. Biliary like and ulcer-like symptoms were more than three times as common in giardiasis as in the controls. There is a high incidence of fatigue and vitamin B deficiency in giardiasis. *Giardia* does not commonly cause diarrhea in adults.

Value of Leukopenic Index in Allergic Diseases—During the last two and a half years, Denny has made more than 4000 studies on individual foods by the digestive leukopenic response method. The mechanism by which leukopenia may develop following the ingestion of a food that acts as an allergen is unknown. He has found the digestive leukopenic

response tests of distinct value in the diagnosis and treatment of patients suffering from food hypersensitivity. Skin testing by the scratch or intradermal methods to the protein extracts of food have limited value. There are some patients in whom the skin is so sensitive that a wheal surrounded by an area of erythema develops at the site of the scratch or intradermal injection of all protein substances to which he is tested, others give no positive skin reactions to any substance tested by the skin method. The determination of the digestive leukocyte response in these groups of patients is a distinctly valuable adjunct in determining the causes of their clinical manifestations.

Decompression After Common Duct Obstruction—

While obstruction of the common bile duct may in itself produce serious cytologic changes in the liver and physiologic changes in the portal venous circulation it is equally true that the rapid release of the obstruction with the sudden inflow of blood into hepatic vessels whose circulation was in varying degrees impeded may lead to equally serious consequences. The intense hyperemia that takes place when a complete ductal obstruction is suddenly released may cause additional damage to the liver cells and changes in circulation. For some years Ravdin and Frazier have used the following method of decompression after the release of an obstructed common bile duct. As soon as the T tube has been sutured in the common duct and bile begins to flow from it, it is clamped. When the patient returns to the ward the clamp is removed and the tube

is connected to the sterile decompression apparatus. If a cholecystostomy has also been performed, the gallbladder tube is attached to a similar apparatus. The apparatus board is so fastened as to put the lowest hook approximately on a level with the common duct. The distance between the hooks is approximately 5 cm. For the first twelve to eighteen hours after operation the Y tube is hung on the top hook approximately 25 cm above the level of the common duct. The usual result is that only a little bile is forced over into the drainage bottle with respiratory movements. The Y tube is then moved downward, but if, at this level, a large amount of bile is drained externally this can be lessened by raising the tube again. By thus adjusting the level of the apparatus the amount of bile drained externally can be regulated. Enough is obtained daily for analytic studies and the remainder is forced down into the duodenum by controlling the level of the Y tube. Thus, as the postoperative traumatic edema of the ductal wall subsides the level can be lowered, but in order to overcome the sphincter tone a certain amount of pressure must always be maintained by keeping the Y tube on the second or third hook. That the bile is passing into the duodenum can readily be determined by frequent observations of the patient's stools and repeated van den Bergh determinations. The forcing of bile into the duodenum, once the obstruction is relieved which prevents the loss of bile to the exterior, is of great value. It is necessary only that the pressure from the decompression apparatus be sufficient to overcome the tonus of the sphincter mechanism at the lower end of the common bile duct for the bile to flow freely into the duodenum. The loss of fluid and electrolytes when the bile is drained to the exterior is considerable, but of even more importance is the loss of the intestinal functions of the bile. In the method advocated, the bile enters the duodenum by its normal route. Appetite improves rapidly and pancreatic asthenia has not been observed during convalescence.

Disruption of Abdominal Wounds—To establish correct figures for the incidence of evisceration and for certain factors that may affect it, Glenn and Moore made a study of the incisions in 2,927 abdominal operations. Twenty-two cases of evisceration were disclosed—an incidence of 0.75 per cent. Catgut was used in closing 1,608 wounds, silk sutures in 1,144, and silver wire in 175 cases. Mid left rectus and transverse rectus incisions are rightfully used with great reserve, for the incidence of evisceration in both is high. Of the usual incisions in the upper part of the abdomen, the upper left rectus carries the highest percentage of disruptions in this series. Only one McBurney wound disrupted in this case the closure was inadequate and the drains were of such bulk as to prevent the wound from closing. Malignant conditions seriously affect the incidence and results of evisceration. There were six eviscerations in patients operated on for malignant disease they comprised 27 per cent of the total eviscerations. In 582 laparotomies for malignant manifestations there were six eviscerations, but in 2,345 operations for nonmalignant diseases there were sixteen eviscerations. Of the sixteen eviscerations in the nonmalignant cases six followed cholecystectomies, the ten other eviscerations were associated with operations for peptic ulcer, postoperative hernia, ulcerative colitis diverticulosis of the colon, bleeding from the gastro intestinal tract, appendicitis with peritonitis and pancreatitis. Debility has been recognized as a possible cause of evisceration. It was present in eleven of the twenty-two cases. In no instance was jaundice or diabetes associated with the evisceration, although these conditions have been encountered frequently in surgical cases. Evisceration occurred thirteen times in incisions of the upper right rectus twice in the upper left rectus once in a transverse rectus once in a mid left rectus, once in a McBurney, twice in lower left rectus and twice in lower right rectus incisions. The single transverse rectus incision disrupted seven days after operation. Of the twenty-two eviscerations eleven were wounds closed with catgut seven with silk three with through and through silver wire and one with through and through silkworm gut. Disruption occurred from one to sixteen days after operation, the majority on the fifth to the eleventh day after operation. Secondary closures were effected in eighteen of the twenty-two cases with through and through silver wire sutures. None of

these reopened. In two cases the wounds were packed and strapped with adhesive tape and in two the wounds were resutured. Following secondary closure, the patients remained in the hospital from nineteen to twenty-six days. The immediate mortality in this group of cases was 45.45 per cent (ten cases). A follow up of the discharged patients showed that one died eight months later of cirrhosis of the liver and another twenty-two days later as the result of cancer.

Treatment of Thrombophlebitis—Murphy has observed thirty-three cases of thrombophlebitis for more than a year in the treatment of which acetyl-beta-methylcholine alone was used. These patients had had the thrombophlebitis for from one week to twenty years without relief from any previously used treatment. The average age of the patients was 52.6 years. The average number of treatments given was fifteen, with a minimum of four in one case and a maximum of sixty-three in one case. No selection of cases was undertaken. A standard 0.5 per cent solution of acetyl-beta-methylcholine chloride is used. Reinforced asbestos paper saturated with the 0.5 per cent solution of the drug is wrapped around the foot and leg as high as the thigh. A malleable metal plate is placed over the wet asbestos paper and is connected to the positive pole of a galvanic machine. A large, regular, moist electrode is used as a dispersive electrode. This is placed under the back and is connected with the negative pole. The current is turned on slowly and increased to 20 or 30 milliamperes. At the end of the treatment, the current is slowly reduced and turned off. Treatment is given in some cases daily, but generally for from twenty to thirty minutes two or three times a week. Systemic reactions constitute an exact duplicate of the reactions following the subcutaneous or intravenous administration of the same drug but are more certain, more prolonged and more easily controlled. They are rarely noted with iontophoresis except in the mild form. In addition there is a characteristic local reaction directly under the site of the application of the drug. This consists of (1) a feeling of prickling followed by warmth during the treatment, (2) the appearance of goose flesh immediately after the removal of the asbestos paper, (3) a local blush of the skin, (4) sweating of the skin, which may continue for from six to eight hours, and (5) an elevation in surface temperature during treatment, followed by a drop during profuse sweating (with accompanying evaporation) and a rise above the former level in from one-half to five hours. Neither the general nor local effects noted can be produced with the use of saline iontophoresis or by the galvanic current alone. Acetyl-beta-methylcholine chloride solution with the use of the galvanic current must therefore be responsible for the effects. Individuals vary in reactions. Some patients who scarcely react to the first treatment show an increasing reaction to subsequent treatments. Thirty-one patients were definitely improved and were able to get about with ease and without the aid of any supporting bandages. Of 488 treatments given, not one untoward reaction was noticed. Cases in which there was lymphedema cleared up remarkably in a comparatively short time after years of progressive discomfort. Associated varicose ulcers healed readily. The two patients with unsatisfactory results had received too few treatments to give the method a fair trial.

Effect of Guinea-Pig Passage on Virus of Rabies—Hurst finds that in both the rabbit and the guinea pig rabies follows intravenous and intramuscular inoculation much more constantly and readily if the infecting material is guinea pig brain than if it is rabbit brain. This phenomenon is not due to any property inherent in guinea-pig brain itself. The ratio between the minimal cerebral infecting dose and the minimal intravenous infecting dose is much lower with guinea pig virus, by expressing the observations in this form, it is at once made obvious that the number of infective units of guinea pig virus needed to infect by the intravenous route is much smaller than of rabbit virus, and the former can be said truly to be more virulent for peripheral inoculation than the latter. This effect of guinea-pig passage was seen only with viruses that were some passages removed from street virus, when recently isolated, the Moroccan strain apparently behaved in a quite different manner, though the results were highly irregular and difficult to read. No evidence was obtained of local multiplication of guinea-pig (or rabbit) virus at a site of intramuscular inoculation.

Road Dust and Primary Lung Tumors—Campbell has shown previously that dust from tarred roads causes cancer of the skin in mice. Road dust minus tar, as removed by benzene, does not cause cancer, it stimulates the production of tumors of the lung in mice, but not to so great an extent as when the tar is also present. Tumors of the lung are rare in mice before they are 12 months of age. The dust does not cause any obvious inflammatory reaction—apart from the tumors themselves—in the lung or lymph glands. Tar, either by a direct action on the lung itself or indirectly by some action on other tissues, or both, stimulates the production of tumors of the lung in mice and hastens their appearance. Metastases from tumors of the lung in mice are recorded, for the first time in this country so far as the author knows. The majority of the tumors of the lung in the dusted mice are malignant.

Dendritic Ulcer of Cornea and Herpes Facialis—Neame describes three cases which presented (1) facial dermatitis herpetiformis with fever, associated with dendritic ulcers (2) herpes around the mouth and on the eyelid, with a dendritic ulcer and two spots that may be classed as nummular or macular keratitis, and (3) typical superficial punctate keratitis with two small dendritic ulcers near the margin in company with a lesion of herpes facialis on the right side of the chin. It is probably true that herpes simplex is a virus disease. The author claims that the cases described are not merely rare.

coincidences but that they support the contention that many cases of superficial punctate keratitis and its grosser forms—nummular or macular keratitis—and dendritic ulcers of the cornea are the result of infection with a virus capable of producing herpes simplex. If one virus is responsible for such a variety of lesions as herpes simplex corneae, superficial punctate keratitis, nummular (or macular) keratitis, dendritic ulceration, disciform keratitis, some forms of neuropathic keratitis and perhaps also keratitis profunda, it must be capable of varied behavior at different times and in different places. One virus—modified perhaps in different localities or in different years—is capable of producing a variety of lesions of the cornea. Confusion may arise from the use of terms that have a different meaning to different persons. Use of the corneal microscope should help in the avoidance of such discrepancies.

Treatment of Lupus Vulgaris with Hydnocarpates—Wallace used intradermal injection of esters of hydnocarpus oil in the treatment of fifteen patients presenting extensive lupus vulgaris who attended a tuberculosis dispensary. Their previous treatment had consisted of local and general artificial light therapy and occasional "spiking" with acid nitrate of mercury, but the lesions had mostly reached that curiously resistant stage in which the disease appears to be neither advancing nor healing. All other forms of treatment were stopped at the commencement of the new method. The length of treatment has varied in individual cases from six months to three years, although, in the longer cases as the condition improved, injections have frequently been spaced out at fortnightly or even monthly intervals. Progress has undoubtedly been more rapid than that made by artificial light treatment alone, but there is no reason why the injections should not be supplemented by general carbon arc baths, as in some of the cases reported by Burgess. Reactions are definitely less painful than those resulting from the usual caustic applications. The intradermal injection of hydnocarpates appears to offer certain advantages over other routine methods. The total amount of the weekly injection has not exceeded 1 cc of phenyl-ethyl hydnocarpate. Reactions can be diminished by spacing the wheals as far apart as possible, and no area should be injected a second time until all inflammatory changes have subsided.

Treatment of Malaria in Children with Atabrine-Misonate—The difficulty in giving quinine by mouth, because of its bitterness, prompted De to use the two intramuscular injection method of treatment with atabrine in the treatment of fifty children. This treatment controlled the clinical symp-

toms rapidly and the effect on temperature was remarkable. The treatment freed the peripheral blood of malignant tertian infection earlier than benign tertian. It did not destroy crescents nor did it prevent their formation. Posttreatment complications (convulsions in five cases and restlessness with vomiting in one case, but no immediate fatality) were unexpected and caused anxiety. There was no abscess formation and no inflammatory reaction in any case. The dose given (0.1 Gm of injectable atabrine dissolved in 3 cc. of distilled water and injected into the buttock) seemed adequate for the average children of from 6 months to 6 years. Taking all the conditions into consideration it is concluded provisionally that two injections of atabrine can be regarded as an efficient course of treatment in cases of acute malaria and its complications in children. The rapidity with which the temperature of the patients is controlled and the facility of administration of this method of treatment are really distinct advantages. The drawbacks to its employment that must be considered are the toxic after-effects in some cases.

Acetylcholine in Treatment of Uterine Inertia—During the last two years Bell and Playfair treated twenty-three cases of severe uterine inertia by intramuscular injections of acetylcholine. The present position in the physiology of acetylcholine appears to be that this substance is intimately connected with parasympathetic nerve stimulation. A patient was considered suitable for treatment when labor had lasted at least forty-eight hours, whether with weak pains or with colicky uterine contractions. Only patients in whom pregnancy had been normal and in whom there was no evidence of disproportion were regarded as suitable for treatment. All patients had previously received treatment with sedatives and attempts at stimulation with enemas, and only when such measures proved unsuccessful in advancing dilatation of the cervix was acetylcholine used. The dosage used was purely empirical and therefore the amount varied. The most effective method was found to be four doses of 0.2 Gm of acetylcholine given intramuscularly at intervals of three hours. The full dosage should be given in all cases, even though the inertia appears to have responded to treatment before the fourth dose has been given. The drug had no harmful effect on the maternal blood pressure, the fetal heart rate, the type and frequency of contractions, the dilatation of the cervix, or the general effect on the patient. The maternal mortality was (one) 4.34 per cent and the fetal mortality was (three) 13.04 per cent (two of these fetuses were dead before acetylcholine was given). Most patients showed a slight temporary fall of blood pressure following each injection. The cervix was fully dilated within twenty hours from

the initial dose of acetylcholine in seventeen cases and within thirty hours in four cases. In two cases the time was longer than thirty hours. In no case did the second stage of labor last more than three hours.

Continuous Drip Transfusion in Gynecology and Obstetrics—Winterton employed the continuous drip blood transfusion in twenty patients in the gynecologic and obstetric department of the Middlesex Hospital. These patients between them received 40,020 cc (70 pints) of blood during 433 hours. The material is insufficient for an attempt at statistical conclusions, but the results in individual cases have been so encouraging that their publication appears warranted. The introduction of such amounts by ordinary methods would result in gross increase of the blood volume causing cardiac failure consequent on overloading of the circulation. It was found that, if blood was introduced at a rate so slow that the hemoglobin percentage was raised by not more than 18 per cent in four hours, the blood volume adjusted itself by the extrusion of plasma and large transfusions could be given safely. A rate of 40 drops per minute is equivalent to a pint of blood in four hours, i. e., a rise of 10 per cent of hemoglobin in an adult. This rate should be regarded as the maximal permissible rate of administration to a nonbleeding patient who is to receive several pints of blood. In a patient who is bleeding, the hemoglobin should still be increased by 10 per cent over four hours. This means that such a patient must receive a pint of blood in four hours plus a quantity equivalent to that being lost. These large transfusions necessitate a number of donors for each case. The onus of responsibility is firmly left to the relatives. Of 390 donors in a series reported by Marriott and Kekwick, 333 were found by the relatives. Blood transfusions should be reserved for those preoperative cases which are so urgent that the patients cannot wait several weeks while their blood is restored to normal by hematopoietic remedies. Eight patients were given preoperative drip transfusions. The average initial hemoglobin of the cases was 36 per cent, and the average hemoglobin after drip transfusion was 76 per cent, the average rise of hemoglobin being 40 per cent from 2,270 cc of blood. The operations consisted of four hysterectomies, two laparotomies for inoperable growths, an incomplete miscarriage and a case of menorrhagia in a patient with jaundice which cleared up after transfusion. Six patients received drip transfusions prior to radium treatment. The total amount of blood transfused was 10,480 cc during 135 hours. The average initial hemoglobin of these patients was 47 per cent. The average hemoglobin after drip transfusion was 78 per cent, an average rise of 31 per cent. The improvement in the general condition of all these women was very striking. In the other six patients, drip blood transfusions were used postoperatively in two for hemorrhage, for postradium hemorrhage in two and in one each for antepartum and postpartum anemia.

*Erysipelas Treated with Prontosil. G. E. Breen and I. Taylor—p. 1334

The Treatment of Streptococcal Infections with 4, 4'-Diaminodiphenylsulfone—Buttle and his co-workers report results which show that 4, 4'-diaminodiphenylsulfone is much more active than sulfanilamide in curing streptococcal infections of mice, and that, while it is more toxic for mice than the latter compound, it is not more toxic for rabbits and monkeys, except that it causes methemoglobinemia more readily in the monkey.

When the diaminodiphenylsulfone is added directly to monkey or human blood in vitro, it appears to be slightly more effective than sulfanilamide. Further, when the drugs are given by mouth to normal monkeys, the maximal bactericidal effects obtained in the blood are of the same order in all cases, although the action of the diaminodiphenylsulfone is more persistent. Therefore it is somewhat difficult to understand why mouse infections are cured by doses of the diaminodiphenylsulfone so much smaller than those required with sulfanilamide. The latter is absorbed and excreted very quickly by the mouse and the concentration in the blood falls to about one tenth of its initial value in seven hours and to one hundredth of this value in thirteen hours; it seems probable, therefore, that there is not a uniformly high bactericidal effect. The experiment with the monkey suggests that the bactericidal effect of the diaminodiphenylsulfone, on the other hand, is maintained. This persistence of the bactericidal effect may account in part for the difference between the drugs, but it seems unlikely that it is the only factor concerned. It is highly improbable that either the diaminodiphenylsulfone or the dimetarsulfone could give rise to *p*-aminobenzenesulfonamide in the body, and their activity is of special interest since it indicates that streptococidal activity is not confined to drugs which contain, or could easily produce, substances containing a sulfonamide group.

Erysipelas Treated with Prontosil—Of their forty-five cases of erysipelas (forty-one of the facial variety), Breen and Taylor used prontosil in one or another form in thirty-five. All patients were in addition painted locally twice daily with a mixture of glycerin and ichthammol. There were two deaths. Of thirty-five patients treated with prontosil from admission, thirty-three had regressed, one had spread and one was stationary forty-eight hours later. There was one subsequent relapse. Of the ten control cases not treated with prontosil, four had regressed, five had spread and one was stationary forty-eight hours later. There were no relapses. Of the five cases which had spread, three were subsequently treated with prontosil, and within forty-eight hours they had also regressed. The average temperature of the prontosil cases fell to normal or below in forty-eight hours, whereas the average of the other cases remained above normal. As regards the pulse, the advantage lies with the no prontosil group, but as they were clinically milder cases, this was reflected in the lower temperature and pulse rate on admission. The drug was administered by mouth in all but two patients, two tablets of sulfanilamide of 5 grains (0.3 Gm.) each were given three times daily to adults, smaller doses proportionately to body weight being given to children. The single relapse in the prontosil group occurred on the tenth day, but this yielded so promptly to a resumption of treatment that the patient was discharged a week later. The average length of stay in the hospital in the prontosil cases was 18.4 days, which compares favorably with the figure of 23.8 days in the other series.

Simple Nonsphincteric Spasm of the Esophagus—McGibbon and Mather believe that, anatomically, spasm that develops at either the upper or the lower (sphincteric) extremity of the esophagus can be regarded as distinct from that arising in the intervening (nonsphincteric) part, although their pathologic condition probably is similar. Simple nonsphincteric spasm may affect one or more segments of the esophagus in its entire extent or a varying portion of its length. Localized spasm and diffuse spasm (tetanic [total and partial], irregular and functional diverticula) have been encountered. Each type may vary considerably in the same and in different patients and occasionally the various types may occur in the same patient. As a rule all types of spasm are transient—there is only a tendency to spastic contraction of the esophageal muscles, and when this does occur it is of short duration. Simple nonsphincteric spasm of the esophagus is a neurogenic manifestation.

festation. It might be caused by an abnormal increase of stimuli traveling by way of the vagi, by a decrease or cessation of impulses by way of the sympathetic, or by an imbalance of the two sets of impulses. The spasm is not commonly diagnosed, as probably in many cases the condition is of short duration and its symptoms are evanescent. Many theories on the cause of simple nonsphincteric spasm have been advanced, some of which are congenital inferiority of the sympathetic nervous system, nervous instability, disorders of deglutition, organic disease of the central or peripheral nervous system, and reflex stimulation from lesions of the thoracic and abdominal viscera. Simple nonsphincteric spasm may give rise to no symptoms whatever and then again it may be discovered accidentally. More commonly intermittent dysphagia and pain on swallowing are the main features, and the pain varies in character from a dull substernal ache to severe shooting paroxysms, which occasionally occur spontaneously and awaken the patient at night. These symptoms may be accompanied by a feeling of anxiety and sometimes by palpitation and dyspnea. During the acute phase swallowed material is regurgitated and regurgitation is the predominant symptom of spasm in children. The routine roentgen examination of the esophagus is made with the patient standing in the left posterior oblique position so that a clear space can be seen between the cardiac and aortic shadows anteriorly and the shadow of the vertebral column posteriorly. The head is turned slightly toward the left shoulder and the chin raised to obtain a clear view of the pharynx. The patient is given a spoonful of opaque food of the consistency of thick cream, and the passage of the opaque bolus is then watched through the pharynx and esophagus into the stomach. If no abnormality is detected, the patient is questioned as to the exact character of the food which gives rise to dysphagia and the consistency of the opaque food is altered or crumbs of toasted bread are added and the examination is repeated. Roentgenograms are taken immediately after the screen examination and also with the patient standing in the right posterior oblique and anterior positions as an abnormality may be demonstrated more clearly in either of the latter positions. When spasm is demonstrated, it is advisable to repeat the examination later in the day on the following day, and perhaps at a later date. If simple nonsphincteric spasm does not resolve spontaneously, all the possible causative factors must be sought for in each patient and if found the appropriate psychologic, therapeutic or surgical corrective measures adopted.

Leptospirosis of a Mild Type in Queensland.—Clayton and Derrick describe a case of seven day fever in a patient living near Pomona, South Queensland. The diagnosis of the case was based clinically on the similarity of the patient's symptoms to those of the seven day fever of the East, and pathologically on the isolation of a leptospira from the patient's blood. This leptospira proved to be different from a strain isolated in North Queensland. It was distinguished by its lower virulence and the absence of cross agglutination. There exist therefore in Queensland at least two distinct kinds of leptospiral disease—the milder seven day fever, and the more

severe kind with frequent jaundice and occasional deaths first described two years ago by Morrissey. Preliminary work suggests that the Pomona leptospira is related to the Rachmat and Baermann leptospiras of Sumatra. This would appear to be the first proved case of seven-day fever in Australia, although the presence of this mild type of leptospirosis has previously been suspected. While only one case has been proved by laboratory tests, there is clinical evidence that a number of cases have occurred from year to year in the same locality which therefore presents an endemic center of seven day fever.

Clinical Study of Rheumatic Fever.—Chang and Dieuaide present a clinical study of 141 cases of rheumatic fever and chorea. The incidence of rheumatic fever and chorea among the medical admissions was 0.57 per cent. The sex incidence seems to vary with age. The ratio, male to female, was 1:1.36. The earliest attack was recorded for a Chinese patient less than 3 years of age, and the youngest foreigner was in the hospital at the age of 3½. The largest and second largest five year groups were those of from 15 to 19 and 10 to 14 years of age, which comprise 42 per cent of the total. The onsets before the age of 30 constitute 82 per cent of the whole. The distribution of attacks in the patients was greatest in January. The onset of the disease is often vague and probably is frequently quite unnoticed. Infections of the upper part of the respiratory tract preceded attacks of rheumatic fever in sixty-three cases. The principal clinical phenomena shown by this group of patients were that 92 per cent of the series had polyarthritides, 64 per cent cardiac disease, 97 per cent fever and 83 per cent leukocytosis. Information about the course of rheumatic fever is limited. Nevertheless, some of the records are of considerable interest from this point of view, since thirty-two patients have been seen for more than a year and twelve of these for more than five years. The average number of days symptoms were present is 33.4, but the most frequent number is twenty-four. The average number of days in the hospital is 36.4, while the most frequent is again twenty-four. Of all admissions twenty-five lasted more than two months. Of the twelve cases of chorea included in the series the ratio of cases of chorea to others of rheumatic fever is low, 1:11. The material included an inadequate sample of the ages from 6 to 12 years. Rheumatic fever, aside from chorea, was diagnosable in all but two of these cases. In two patients before they had chorea, in seven during chorea and in one instance after chorea. Four patients had joint pains. The heart was clearly affected in six cases, and possibly so in three others during chorea, another patient subsequently developed severe cardiac disease.

I. Wugmeister—p. 535

Treatment of Hypertrophy of Prostate with Estrogen—Wugmeister maintains that hypertrophy of the prostate is due to a hypervirilization of the organism, which takes place during the presenile age because of a deficiency in estrogen. When the anterior hypophysis is no longer inhibited by the estrogen it produces an excess of its gonadotropic hormones, which in turn stimulate the genital glands. The glandular tissue which responds most to this stimulation is that of the periurethral glands and, if the excessive production persists for long periods, hypertrophy of the prostate results. The author admits that this hypothesis is in complete contradiction to that of several other investigators, who maintain that the hypertrophy of the prostate results from a deficiency in testis hormone and a predominance of the estrus-producing hormone. He points out that if the latter theory corresponded with the facts the injection of large doses of estrogen would result in an aggravation of the symptoms of hypertrophy of the prostate. This, however, is not so. On the contrary, large doses of estrogen effect an amelioration of the condition. The author resorted to the administration of large doses of estrogen in twenty-three cases of hypertrophy of the prostate. In sixteen of these cases the improvement was marked: there was a diminution in the nocturnal pollakiuria (one or two nocturnal micturitions instead of the former four or six), an improvement in the difficulties at micturition and a reduction in the residual urine. In four other cases the residual urine remained unchanged but the subjective symptoms were considerably improved. The three remaining patients were not improved. Regarding the method of the treatment, the author says that it must be continued for at least twelve weeks and that at least 100,000 international units of estrogen must be injected per week. At first the weekly dose may even be 200,000 units, but as improvement becomes noticeable the weekly dose can be diminished to 10,000 units.

Specific Toxoid Therapy of Staphylococcal Disorders

—Ramon and his collaborators review the status of the specific toxoid therapy of staphylococcal infections. They find that in the cutaneous staphylococcal infections the results obtained by means of staphylococcal toxoid are satisfactory and that in the future the toxoid therapy of osteomyelitis and of staphylococcal septicemia promises even better results. In tropical regions, where staphylococcal infections are especially severe, the toxoid therapy is likewise the method of choice. To be sure, the authors admit that in other countries, such as England and the United States, the results with staphylococcus toxoid have been disappointing, but they think that this is due to insufficient dosage.

Diagnosis of Diphtheria in Vaccinated Persons—Reh shows that in persons who have been vaccinated against diphtheria it is necessary to consider the following possibilities: banal disorders in the presence of the pseudodiphtheria bacillus, disorders in immunized persons, and true diphtheric disturbances developing in persons who have been insufficiently immunized. The etiologic and immunologic differentiation of these cases is important for the treatment or the prophylactic measures. The microscopic examination is usually sufficient for the bacteriologic diagnosis of diphtheria in the nonvaccinated, in whom the diagnosis had usually been suspected on

the basis of the clinical aspects. However, the problem is more difficult in vaccinated persons, in whom the symptoms usually are not typical, or in bacillus carriers, in whom the symptomatology is nil. The author mentions the following stages as essential in order to arrive at the diagnosis of diphtheria in vaccinated persons: a bacteriologic stage revealing under the microscope the presence of diphtheriform bacilli, an experimental stage demonstrating by inoculation into guinea pigs the pathogenicity of the causal bacilli, and an immunologic stage, which establishes by the Schick test or the skin test the receptivity of the subject. One cannot speak of diphtheria in a vaccinated person without having tested the reaction of the guinea-pig to the bacillus and the reaction of the patient to the Schick test or the skin test.

Roentgenotherapy of Gonorrheal Arthritis—Reports in the literature and his observations of nine cases convinced Nguyen-Dinh-Hoang that roentgen therapy constitutes an efficacious treatment of gonorrheal arthritis. In discussing the technique of this treatment, he says that the majority of authors employ moderately penetrating rays, which are produced by from 120 to 150 kilovolts, filtered by from 5 to 10 mm of aluminum or by 0.5 mm of copper plus 2 mm of aluminum. The intensity varies between 2.5 and 3 milliamperes. The focal distance is from 25 to 30 cm. The number of fields depends on the region. As a rule the fields should be larger than the diseased articulation. The dosage varies according to whether the case is chronic or acute. In the chronic cases the author gives from four to five irradiations of from 150 to 200 roentgens per field, which makes a total dose of from 600 to 1,000 roentgens per field. He returns to the initial dose of 100 roentgens every time he fears a painful reaction. From one to three irradiations are given each week. If the improvement is not satisfactory, a second series is applied after an interval of one month. In acute cases with severe inflammation and pain smaller doses are given, the first dose is usually from 30 to 40 roentgens and the later doses up to 100 roentgens. Five or six applications are generally adequate. If in exceptional cases the first irradiation is followed by an increase in pain and tumefaction, it is not necessary to become alarmed, on the contrary, this reaction indicates favorable ultimate results. The results of the roentgen therapy are favorable. The treatment not only counteracts the pains and the tumefaction but permits early mobilization. The prospects of cure are the better, the earlier the treatment is begun. Even in the forms of arthritis with purulent discharges in which arthrotomy is necessary roentgenotherapy seems advisable, particularly for the control of the pains.

Chronic Atrophic Nephritis of Childhood—Debre and his associates direct attention to a rather curious disease entity which has been described under such terms as renal dwarfism, renal infantilism, renal rickets or chronic atrophic nephritis of childhood with arrest of growth and osseous deformities. They discuss particularly those aspects of the chronic atrophic nephritis of childhood which appeared to them especially noteworthy in their observations in nine cases of this type. After discussing the statural dwarfism, the normal intelligence and the fact that the development of the secondary sexual characters fails to take place at the time of puberty, they report their observations on the phosphorus and calcium metabolism. The phosphorus and calcium metabolism of these children with renal rickets differs from that of children with common rickets. Renal rickets is characterized by a hyperphosphatemia and a hypocalcemia but in spite of the existing hypocalcemia tetany is extremely rare in renal rickets. This has been ascribed to acidosis in renal rickets, which prevents the tetany by transforming the largest portion of the calcium in the ionized form. Regarding the first manifestation of the renal trouble, it is

stated that the majority of authors agree on the period between the sixth and the tenth year of life. Careful observation discloses, however, that some symptoms, such as polydipsia and polyuria, are apparent much earlier. Further, the authors discuss the symptoms of chronic nephritis, particularly in urine and blood. They also call attention to the pallor and to the jaundiced color of these children. On the other hand, the absence of certain symptoms is noteworthy. The cardiovascular reaction is generally reduced to a minimum, there is neither arterial hypertension nor disorders of cardiac decompensation nor vascular changes in the fundus of the eye. In discussing the pathologic anatomy of this disorder, the authors give their attention chiefly to the renal lesions. They differentiate six forms of this renal disorder and give a summary report of the characteristics of each group.

Justa Articular Nodes Clinical Study C Pisacane — p 308

Cutaneous Symptoms of Monocytic Leukemia—Sannicandro reports a case of monocytic leukemia in a man, aged 37. The patient showed cutaneous nodules, macular infiltration and subcutaneous hemorrhages all over the body, but more abundantly at the thorax, as well as hepatosplenomegaly and enlargement of the superficial lymph nodes. The hemogram was that of leukemia with great increase of monocytes. The cutaneous infiltrates were characterized by a predominance of monocytes. Repeated examinations of both recently formed and old developed cutaneous lesions failed to show hyperplasia of the reticulo-endothelial system and local formation of monocytes. The author reviews the literature on the subject and discusses the several histogenic theories of the disease. He concludes that the origin of monocytic leukemia may be reticulo-endothelial or myeloid (hemocytoblastic). In the last case the cutaneous infiltration is of metastatic origin. According to the author, it is advisable to designate the disease as monocytic leukemia with cutaneous symptoms rather than as reticulo-endotheliosis.

*Modified Prefunicular Technique for Operation of External Oblique Inguinal Hernia O De Souza Nazareth — p 91

Technic for Operation of Inguinal Hernia—De Souza Nazareth's technic of prefunicular operation of external, oblique inguinal hernia is as follows. The incisions of the skin and of the aponeurosis of the large oblique muscle are the incisions generally used for inguinal herniorrhaphy, and the transverse fascial is exposed and incised over the seat of the hernia together with the common fibrous layer over the inguinal cord. The peritoneum is maintained under slight traction all through the following steps of the operation. The hernial sac is isolated

above its neck and removed as high as possible, the ligation being made above the neck of the hernial sac. Removing the hernial sac at a high point and maintaining a slight constant traction during the operation are of importance in preventing recurrences. The stump of the hernial sac is then pushed deep into the inguinal orifice and anchored in subperitoneal tissue under the fascia (Barker maneuver) by means of the ends of its ligature. Removal of the hernial sac leaves a space in the deep inguinal orifice. The space is reduced by two sutures, only the necessary opening being left for passage of the inguinal cord. The transverse fascia is doubled like a pleat placed over the inguinal cord and fixed to the crural arch by means of chromic catgut. The inguinal cord is thus protected by a double fibrous layer of the transverse fascia. The upper border of the abdominal muscles is sutured with No 2 or 3 chromic catgut in one plane to the crural arch. The lower border of the external oblique muscle is then sutured over the previous plane and the skin is closed. By the technic the abdomino-inguinal wall is firmly reconstructed and there are no recurrences of the hernia.

*Pathogenesis of So Called Spontaneous Ruptures of Spleen and Remarks on Symptomatology E Ask Upmark — p 897

Malaria Plasmodia and the Reticulocytes—Malamos shows that there are contradictory statements in the literature regarding the penetration of the malaria plasmodia into the reticulocytes. Eaton and Jakobsthal maintain that the largest number of malaria parasites are found in the reticulocytes. The author made studies on the blood specimens of malaria-infected monkeys and human subjects. Tabular records of the results of these tests indicate that only a small portion of the plasmodia are found in the reticulocytes. The percentage of the cells with vital granulation, which contained plasmodia corresponded approximately to their percentage in relation to the other erythrocytes. A special affinity of the malaria plasmodia for the reticulocytes could not be detected. The author further investigated Hingst's assertion that Schüffner's stippling is of a reticular nature. Hingst had based this assertion on the observation of a transition between the blue-stained reticular stippling to the red-stained Schüffner stippling. In careful studies on Schüffner's stippling, Malamos never observed a transition between this and the reticular stippling. He found that Schüffner's stippling has a distinct and regular red coloration whereas the reticular staining shows a more irregular bluish color. However, he was unable to determine the true nature of Schüffner's stippling.

So Called Spontaneous Ruptures of Spleen—Ask-Upmark points out that so called spontaneous rupture of the spleen has given rise to many discussions. It has been generally conceded that spontaneous ruptures do occur in certain pathologic changes of the spleen such as exist in malaria, typhoid, leukemic splenomegaly and splenic congestions. The possibility of a traumatic, so-called two-stage rupture has likewise been generally recognized. However, the opinions are divided about the spontaneous rupture of an intact spleen. In reviewing the records of spleen ruptures that came up for observation in Swedish hospitals the author obtained information about the symptomatology of splenic ruptures and about the occurrence of spontaneous ruptures. He found that the so-called spontaneous splenic ruptures in some cases can be traced to a traumatic etiology (two stage ruptures) and in other cases to pathologic changes within the organ. In addition to this there is the possibility of spontaneous rupture of a spleen that from the morphologic point of view is essentially normal. The author suggests that in these cases a circulatory disturbance of functional origin may be the cause, which leads to hemorrhage and then to rupture. In discussing the symptomatology of rupture of the spleen, the author says that the general con-

dition presents the aspects of a progressive internal hemorrhage. The local symptoms frequently show certain peculiarities. Pains that radiate toward the left axilla point to the spleen, but these pains may also radiate toward the right side, they may be elicitable by pressure on the splenic region and may be influenced by the posture. The abdominal pains that occur in rupture of the spleen often have a periodic character. Occasionally pains and sensitivity are found in McBurney's region.

Vitamin Treatment of Funicular Spinal Disease—Pfaffenberg and Mielke direct attention to the successful treatment of neuritides of various types and of funicular spinal disorders by means of vitamins of the B group. After reviewing the literature they describe their own favorable experiences with B₁ preparations in the treatment of funicular spinal disorders. They found that the motor disorders are most favorably influenced. Regarding the advisability of the oral or parenteral B₁ therapy they say that either might be effective in some cases but that there are others in which oral yeast medication will fail and only the injection of the vitamin preparation will produce the desired results.

Therapeutic Use of Alpha Rays in Acute Gonorrhea—Nagell and Noethling say that the knowledge of the superior efficacy of the alpha rays compared to the beta and gamma rays is almost as old as the knowledge of radioactivity itself. Moreover, investigators have called attention to the especially great sensitivity of gonococci to the bactericidal effect of alpha radiation. Others proved that a combination of thorium solutions with silver salt solutions had a greater bactericidal effect than either of the solutions alone. To be sure, the exact quantitative evaluation of the physiologic action of the alpha radiation involves many difficulties. The authors discuss some of the problems that remain to be solved and point out that as yet it cannot be definitely stated whether the bactericidal effects of the alpha rays can be utilized in practice. Investigations toward this aim are being continued, but it remains to be determined how the adjoining tissues will react and whether technical difficulties will be encountered in the exact and safe application of the necessary density of rays. Regarding the harmfulness for the adjoining tissues, the prospects are not as hopeless as in the bactericidal action of roentgen and gamma rays. They are not poorer than they are for chemicals and there is a possibility that they are better. Moreover, the quantities or concentrations of alpha ray emitting radioactive substance, which can be computed from the results on the bactericidal action, are within the limits of technical possibility.

Masked Meningococcic Sepsis—Kummerling describes the clinical history of a woman, aged 45, who was hospitalized with the suspected diagnosis of paratyphoid. However, careful clinical examination and observation excluded typhoid, paratyphoids, dysentery, Brucella abortus infection and military tuberculosis. The patient's symptoms changed constantly. The fever was intermittent and every increase in temperature was accompanied by a skin eruption, which likewise changed in appearance and localization. The general condition was comparatively favorable but the patient complained of severe head-

aches whenever the fever increased. Foci of infection could not be found and repeated blood cultures remained sterile, until finally one revealed diplococci, which exhibited the behavior of meningococci and agglutinated with a meningococcus serum. Following the definite identification of the cocci the patient was given 20 cc of meningococcus serum by intravenous injection and the same quantity by intramuscular injection. On the following day the temperature subsided and the exanthematous crops ceased. Two days after the first serum injection the patient was given another intramuscular injection of 40 cc and was finally discharged as cured. This case was reported in detail because this symptomatology readily causes erroneous diagnoses. Particularly in children, it may be confused with the so-called internal measles. Meningococci should be searched for, especially since early serotherapy is of greater importance in young persons, who are less resistant to meningococci than adults.

Cause of Complications After Short Wave Treatment—Liebesny points out that he and his collaborators observed in 1931 and 1932 that, when short waves were used which produced considerable thermic effects, vascular damage was likely to result. It was observed also that the use of longer waves results in more severe vascular changes than does the use of shorter waves, for the reason that the longer waves produce greater thermic effects. In this paper the author tries to determine whether complications that appear after short wave therapy can be brought in causal connection with the rays when an excessive dosage can be definitely excluded. He shows that in two cases of his own observation and in three cases from the literature an excessive dosage with harmful thermic effects is out of the question and that therefore a causal connection between the short waves and the symptoms mentioned cannot be assumed. He admits that, if harmful effects develop in rare cases after the use of small doses, it might be suggested that in some persons the tissues have a hypersensitivity to short waves. In order to solve this question, further investigations will be necessary, for observations thus far do not justify such an assumption. Moreover, the author suggests that the complications may be due to the peculiarity and the localization of the condition treated, that is, they develop in spite of the short wave therapy rather than because of it.

*Peripheral Radial Paralysis After Burns G Bahls —p 857

Radial Paralysis After Burns—Bahls reports the history of a man, aged 32, who sustained burns on the left forearm. The patient himself applied linseed oil and then continued his work for the next two days. However, increasing pain induced him to consult a physician, who treated the burns with ointment. During treatment the patient observed that he could not stretch the fingers of the left hand. This condition persisted after the burns had completely healed and the patient was subjected to a neurologic examination, which disclosed paralysis and atrophy of the extensor carpi ulnaris and of the extensor digitorum communis and weakness of the extensor carpi radialis. A review of the literature failed to disclose a similar case, but in a report by Bettmann the author found neuritis mentioned as a complication of burns. To be sure severe electrical burns have been known to result in radial paralysis, but these burns were much more severe than the ones in the case described. After showing that traumatic and thermic factors could not have produced the paralysis, the author points out that the onset of the paralysis with pains suggests that factors producing a neuritis might be involved in this case. After analyzing the possible causes the action of biologic toxins is regarded as the most probable one, the more so since the case somewhat resembles the plexus paralysis that may result from the injection of tetanus serum or other therapeutic serums. Moreover, investigations by Robertson and others have revealed that in burned tissues a toxin is formed which has two com-

ponents, a neurotoxic one and a necrotoxic one. This toxin, although autogenous, acts like a foreign protein and the author suggests that such a toxin was responsible for the paralysis in the case reported.

*Congenital or Spontaneous Arteriovenous Connections and Their Surgical Significance S Rosenak —p 962
*Clinical Characteristics of Hepatorenal Syndrome A Pytel —p 965
*Sugar Consumption and Diabetes Mellitus B Süsskind —p 968
Cramp Neurosis in New Light A Gross —p 970

Spontaneous Arteriovenous Connections—Rosenak asserts that the arteriovenous malformations are comparatively frequent. In reviewing the literature he found that up to now 400 cases have been reported. The majority of cases involved the central nervous system and 106 cases involved the extremities. It is interesting that forty of these cases have been described in the last six years. This proves that such disorders are not as rare as is generally assumed. The author himself observed two cases within the last year. He describes the clinical aspects and the surgical treatment of these two cases. He shows that the diagnostic methods have been improved in recent years by three new methods: (1) comparative calorimetry, (2) determination of the oxygen content of the venous blood and (3) visualization by means of arteriography. The aim of the treatment should be the interruption of the pathologic arteriovenous connection. This can be accomplished by the injection of thrombosing substances, by the mechanical production of thrombosis, by surgical division of the arteriovenous connections or by the ligation of the vascular trunks supplying the region of the arteriovenous connection. Although these methods may not always produce complete cure, they usually cause long-lasting remissions and prevent crippling operations.

Hepatorenal Syndrome—Pytel says that in recent years a number of clinicians and pathologists have called attention to disorders in which a secondary renal impairment developed after primary disease or traumatic impairment of the liver or to primary renal lesions that led to hepatic complications. The simultaneity of the reaction of liver and kidney to a pathogenic agent indicates a functional relationship of these organs, and the term hepatorenal syndrome has been applied to the disorders in which both organs are involved. The author classifies under the heading of hepatorenal syndrome a large number of disorders, such as the renal changes in cases of hepatic cirrhosis, the renal symptoms in the acute hepatitides that accompany intoxications, the renal changes in acute and chronic diseases of the liver and of the bile passages with and without icterus, the hepatorenal syndrome after acute traumas of the liver, after surgical intervention on the liver and biliary tract and after operation on other abdominal organs, the hepatorenal syndrome in hepatic tumor metastases, the hepatorenal changes in eclampsia, and the hepatic and renal changes in hyperthyroidism in hypertension and so on. The pathologic changes in liver and kidney may be produced by metabolic disturbances or by toxic bacterial or medicinal factors. The author gives his attention chiefly to two forms of the hepatorenal syndrome: (1) that after operations on the liver and biliary passages and (2) that which develops in chronic diseases of the liver and bile passages. He says that the first type usually develops between the fifth and eighth days of the postoperative period. It appears mostly in persons who for years have had calculous or noncalculous cholecystitis. The syndrome usually begins with a rapid increase in temperature, tachycardia and meteorism. Shortly after, a progressive oliguria sets in and the urine contains tube casts and blood. The azotemia increases, whereas the urea content of the urine decreases. The patients are nauseated and vomit and some have hemorrhages from the mucous membranes, so that the vomit and stool may have an admixture of blood. Later extensive edemas develop, the oliguria progresses to anuria, and the patient becomes comatose and dies. After reviewing the literature on such cases, the author cites nine that were observed at his clinic. In discussing the hepatorenal syndrome in chronic diseases of the

liver and biliary passages, he points out that this form of chronic hepatonephritides has not been sufficiently investigated as yet. It has not been definitely determined whether the two organs become simultaneously or successively involved. He analyzes forty-six cases observed at his clinic and differentiates various groups and subgroups of the hepatorenal syndrome.

Sugar Consumption and Diabetes Mellitus—Süsskind cites statistical data which indicate that diabetes mellitus is constantly increasing. He shows that this increase is due to a higher fat content of the diets. The opinion that a diet with a carbohydrate or sugar content is likely to produce diabetes is erroneous. It is important for the prophylaxis and cure of diabetes mellitus that fat consumption be restricted and that it be replaced by carbohydrates. From 40 to 50 Gm of fat in the daily diet is far in excess of the requirements.

Noteworthy Case of Moller-Barlow's Disease S Wolff —p 697

Rare Form of Pulmonary Collapse in Pneumothorax—Abdulkadir-Lutfi reports the clinical history of a youth, aged 18, who was subjected to pneumothorax therapy on account of a tuberculous infiltration and small cavity on the left pulmonary apex. After the first injection of air, the patient felt a slight pain in the left side of the thorax, which persisted during the following night and day and then disappeared. After the second air filling, roentgenoscopy revealed that the region of the left upper lobe was completely filled with air and that the upper lobe lay over the partly collapsed lower lobe. The outlines of the forward tilted upper lobe were quite clear, the apex was below, the base above. In order to determine whether the upper lobe would return to its right position, the fourth refilling of the pneumothorax was followed by an x-ray examination in Trendelenburg's position (head down, pelvis up). In this examination the return of the upper lobe to its normal position could be observed, but as soon as the patient stood up again the upper lobe tipped again over the lower lobe. During inspiration and expiration the apex is lifted upward like a tongue. After attempting an explanation of this unusual form of collapse the author takes up the possible harmfulness. He suggests that the torsion of the lobe could be harmful for the veins and bronchi and might eventually lead to stagnation of the sputum. The patient, however, showed no harmful effects. His temperature decreased and his weight and general condition improved during this peculiar form of pneumothorax.

Action of Transfused Blood in Surgical Diseases—The effect of transfused blood in hemorrhage, according to Gesse, is one of substitution. Nerve centers and cardiac ganglia are relieved from a state of anoxemia and the vascular bed is filled with fluid. At the same time there is noted a hemostatic and stimulating effect. Transfused blood stimulates the heart and the vascular tone more effectively than any pharmacological substance. An important phenomenon in transfusion is the mobilization of reserve depots of blood. In this connection the author prefers to speak not of the amount of blood lost but of the state of circulatory decompensation. The most important test of decompensation is blood pressure determination. Correction of decompensation or of pathologic distribution of the blood takes place in blood transfusions performed for traumatic or postoperative shock. At the same time anoxemia and acidosis of the cells of the entire organism

is removed. The effect of transfusion in cholemia is one of detoxication of the plasma, brought about by the suprarenal and vasoconstrictor-like qualities of the blood. At the same time, calcium and vitamins are introduced in large amounts. The effect in burns is that of combating the shock in the first instance. In the second stage, in which the erythrocytes are destroyed, the substituting and the stimulating effects are present. The detoxicating action diminishes the intoxication due to the broken down albuminous products. The effect of blood transfusion in ileus is that of detoxication and the correction of dehydration. In poisoning the principal effect of blood transfusion is one of detoxication. The concentration of the poison may be diluted to one tenth and in the combination of bloodletting and transfusion to one fifth. The effect is not limited by the dilution of the poison but also extends to its removal from the erythrocytes.

Obstruction of the Bile Tract—Chasovnikov analyzes his material of 237 cases of acute and chronic obstructions of the bile passages. Gallstones accounted for thirty-five cases, in 170 the obstruction was due to stones in association with inflammatory manifestations of the bile tracts and of the pancreas, in eleven cases cholangitis, hepatitis and pancreatitis without stones were the cause of obstruction, in seven cases it was due to stricture of the duct, in ten to malignant tumors, and in four to parasites. Obstruction of the bile passages leads to stasis of the entire biliary tree, to jaundice and, when combined with infection, to inflammatory processes in the bile passages, in the intrahepatic bile ducts and in the pancreas. This causes lowering of the functional capacity of the liver. The prognosis in obstruction due to malignant neoplasms or as the result of congenital atresia or aplasia of the bile tract is bad, even after operative intervention. The prognosis is better in obstruction due to gallstones, parasites or inflammatory processes in the ducts and in the pancreas. The prognosis here depends mainly on the degree and the duration of the obstruction and stasis, as well as on the virulence of the infection and the degree to which the liver, heart, kidneys and the organism in general are involved. The earlier the operative intervention, the better the prognosis. Patients with obstruction of the bile passages should be considered dangerous, requiring a special preparation for the operative intervention. This consists of repeated infusions of a 5 per cent solution of dextrose with insulin, repeated blood transfusions and, in the case of acholic patients, administration of bile into the gastro-intestinal tract. A method of choice in obstruction of the deep bile passages is choledochotomy, with removal of the stones or parasites and primary suture. Drainage of the hepatic or common bile ducts is indicated in the presence of suppurative cholangitis or considerable alteration of its walls. Choledochoduodenostomy is indicated in the presence of an obstruction in the lower portion of the choledochus which cannot be removed, of intrahepatic bile stones and of chronic pancreatitis of long duration. Repeated blood transfusions are indicated in post-operative so-called cholemic bleeding, and in the presence of acholia the introduction of bile into the gastro-intestinal tract is of value. Infusions of dextrose with insulin are likewise valuable. Postoperative mortality in the fresh, uncomplicated cases of obstruction varies from 15 to 5 and even 10 per cent. In the older cases, complicated by a grave infection of the deep bile passages or by malignant neoplasms, the mortality rate is between 15 and 50 per cent. Permanent restoration to health after operative treatment of obstruction of the deep bile passages oscillates between 56.6 and 74.9 per cent. Improvement is noted in from 15.9 to 31 per cent, while failure or aggravation is noted in from 9.7 to 12.2 per cent. Failures of operative intervention are due principally to neglect of the disease and more rarely to errors in the operative technique.

Etiology of Acute Pancreatic Necrosis—According to Solovov, the majority of modern contemporary clinicians regard acute pancreatic necrosis as a disorder secondary to or accompanying cholelithiasis. Vague terms, such as constitutional predisposition or a special reactive faculty of the organism, are invoked to explain the sudden development of pancreatic necrosis in the presence of the most varied types of operative trauma or disease. A consideration of the great frequency of cholelithiasis on the one hand and the great rarity of pan-

creatic necrosis on the other suggests that they do not exist in causative relationship to one another. In 1,278 operations for acute pancreatic necrosis collected by Schmieden, stored in the common duct were found in 19.4 per cent of the cases and in the ampulla of Vater in 6.3 per cent. The mechanical theory of the penetration of the pancreatic duct by the bile as well as the neuromuscular theory with a consequent spasm of the blood vessels, and the necrosis of the pancreas under the influence of the hepatic colic, do not explain the etiology and the pathology of the condition in many cases. The animal experiments have been characterized by crudity and pronounced trauma, so that they only slightly resemble the conditions in man and cannot serve as an analogy. The consideration of the theory of allergens in general and of the pathologic-morphologic picture of pancreatic necrosis convinced the author that the latter is a hyperergic inflammation in an organism previously sensitized by some allergen. What is characteristic in this condition, if it is of allergic nature, is the lack of correspondence between the rapidity and the gravity of the process in the pancreas and the relative insignificance of the provoking cause. This, however, is characteristic of the hyperergic reaction on the part of an organism previously sensitized.

Thrombopenia with Purpura (Werlhof's Disease) After Use of Sedormid P. Van Andel and J. Groen—p. 3348

Epidemic of *Leptospira Canicola*—Roos and his associates report a case of infection with *Leptospira canicola*, which, like an earlier one, was first regarded as a meningitis. However, on the basis of serologic and bacteriologic examinations the disorder was diagnosed as Weil's disease caused by *Leptospira canicola*. The source of infection was probably a young Samoyed dog, which belonged to a litter in which all except one were infected with *Leptospira canicola*. Serologic tests on the members of other families who had one of the litter of Samoyeds disclosed that two other persons had passed through a *Leptospira canicola* infection under a different diagnosis. Moreover, the infection was transmitted to a fox terrier which had come in contact with the litter of Samoyeds. It was determined that the infection spread from the male to the female Samoyed and then to the young ones, the young dogs in turn transmitting it to three persons. The strain of *Leptospira canicola* was obtained from cultures of the urines of one patient and three dogs. It proved more virulent for guinea pigs than had been the case in earlier observations. None of the dogs (none in all) which had the infection were severely ill and none of them died. This seems to indicate that the *Leptospira canicola* infection takes a comparatively mild course in dogs.

Hemorrhagic Purpura After Use of Soporific—Kramer relates the clinical history of a man who was subject to insomnia and who for two or three years had resorted to the use of the soporific sedormid (allyl isopropyl acetyl-carbamide). At first he had used it only occasionally, but later he had used it almost every night. When the patient came under observation he had the symptoms of hemorrhagic purpura. The disorder improved in response to calcium, vitamin C and a diet which provided liberal amounts of fruits and fruit juices. However, after renewed ingestion of sedormid tablets there was a relapse. This definitely established the soporific as the cause of the hemorrhagic purpura. This causal connection seemed the more likely to the author in view of the fact that he recalled another case of hemorrhagic purpura with thrombopenia in which the same soporific had been used. Moreover, a review of the literature disclosed that several similar cases had been reported. He admits that cases of thrombopenic purpura have been observed also after the use of other medications (iodine preparations, arsenic compounds, quinine, antipyrine, insulin serum injections and so on), but he gained the impression that after sedormid such cases were more frequent.

GRADUATE EDUCATION AND TRAINING OF RADIOLOGISTS

B R KIRKLIN, MD
ROCHESTER, MINN

With the relatively recent recognition of radiology as a special branch of medicine and the establishment of an authoritative body to ascertain and attest the competence of radiologic specialists, the education of future radiologists has assumed major importance. To present day radiologists the problem is momentous, because on the quality of training they give will depend the ability of their successors to meet responsibilities to future patients, to medicine in general and to radiology itself.

Pioneer radiologists had to learn slowly by trial and error, by experience that often was bitter. Their pupils, who constitute a large majority of the radiologists practicing today, learned almost exclusively by apprenticeship, and that usually short. For several years more or less systematic courses of graduate instruction have existed at various institutions, but these courses are rather diverse and their relative merits and adequacy have not yet been fully determined. Indeed, until three years ago when the American Board of Radiology prescribed certain fundamental requirements in the education of radiologists there was no uniform base on which courses could be constructed. Thus the whole problem is still so new and has so many angles that much thoughtful consideration will be necessary to solve it satisfactorily and completely.

In brief, the American Board of Radiology requires that the student shall be a graduate from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association, and after 1940 it will be required that he shall have completed an internship of not less than one year in a hospital approved by the Council. His special training in radiology shall comprise not less than three years of study in an institution recognized by the board and the Council and shall include (a) intensive graduate training in pathologic anatomy, radiophysics and radiobiology, (b) active experience of not less than twenty-four months in the radiologic department of the institution, and (c) examination in the basic sciences and clinical aspects of radiology.

It is to be noted well that the board has not attempted to plan a detailed course but has established broad minimum requirements, which, it is to be hoped, will not be taken as standard but will be exceeded, as far as possible. Criteria to be observed in selecting students, the apportionment of the three years of instruction and the subjects to be taught are stated only in general

terms, and methods of teaching are not prescribed. Within the wide latitude thus granted, institutions may plan courses and vary details at will. Concerning some of these details, I am quite willing to offer my views, with the understanding that they will be regarded merely as the opinions of one teacher and with the hope that they will stimulate wise thought and action.

Among all factors involved, it seems to me that the most important is the selection of students for training. Of the many applicants now on the waiting lists of most institutions, only those who seem really to be promising should be accepted. Those who have reached rather mature age, who have failed in other medical fields, who are attracted by the stipend commonly allowed, who appear to regard radiology as an easy road to riches or who plan to cut their training short should be rejected incontinently. On the positive side I consider it essential that the student be young, industrious and keenly interested in radiology and have a natural aptitude for the work. Youth is necessary, for only at that period, as a rule, has the student sufficient alertness and plasticity of mind to acquire thorough knowledge of any specialty. Qualities that I regard as indicative of a natural aptitude for radiology include keenness of observation, marked ability in analysis, a well restrained imagination and a highly judicial temperament. Conservatism in judgment is absolutely requisite for reliable radiologic diagnosis. Shadows are illusive, and the imaginative, impetuous, incautious radiologic diagnostician can do a vast deal of harm. The qualities mentioned cannot be determined from application blanks, certificates and letters of recommendation, however voluminous, and no candidate should be accepted without a personal interview sufficiently thorough to reveal the principal elements of his innate personal equation. Despite all precaution unsuitable candidates will occasionally be accepted, and when the fact is discovered they should be taken off the roll. I lay stress on care in admitting graduate students because it is a practical and effective way of raising radiologic standards and is in line with the increasingly stringent requirements for enrolment in medical schools.

As to apportionment and sequence of the course, there is room for differences of opinion. I feel, however, that not less than six months should be devoted to study of pathologic anatomy, three to technique, twelve to diagnostic interpretation, nine to therapy and six to be applied by the student at will to any branch in which he is deeply interested or feels that he is deficient. This order of periods is desirable but often cannot be followed if the course is arranged on the quarter system.

A thorough knowledge of pathologic anatomy is an indispensable foundation for efficient radiologic diagnosis and treatment, and this part of the course should be given early. It should include study of the gross and microscopic pathology of specimens obtained at opera-

Session of the American Medical Association, Atlantic City, N. J., June
10, 1937.

tion or necropsy, comparison of anatomic with radiologic changes, radiography of cadavers and specimens, observation of the effects of irradiation on tissues, and research into some special radiopathologic problem.

In my experience, students are likely to show less spontaneous interest in technic than in other aspects of the work, but they should be required to spend at least three months in studying and applying the various technical procedures necessary for diagnosis and treatment. During this time they should also receive special instruction in radiophysics and radiobiology, either from lectures or from reading selected textbooks. The twelve months devoted to radiologic diagnosis should be applied to attentive observation in this field, to comparison of radiologic diagnoses with conditions found at operation or necropsy, and, whenever possible, to active participation in special procedures such as salpingography, ventriculography, intravenous urography, and operations controlled by radioscopy. Training in radiotherapy, including both roentgen and radium therapy, should consist of practical instruction in measuring dosage and selecting appropriate technics, together with as much supervised experience as can safely be granted to the student. The final six months of the course, the elective period during which the student is free to give further attention to any feature of the work that he may select, will usually be appreciated and well employed by him. Periodic examinations, as required by the Board of Radiology, are desirable to determine whether the student should continue his training or not. Any student who shows an aptitude for research should be encouraged to make original investigations. Such research often is a suitable basis for the thesis required for an advanced degree. In some institutions a student who has shown marked ability and has finished his course is appointed first assistant for a year or more. Those who receive the appointment with its more direct responsibility usually profit greatly from the experience that it affords.

As to methods of instruction, I am tenacious in the belief that the student should get his knowledge from experience by active participation in the work rather than from didactic teaching, especially that of the formal type. The informal seminar, at which a series of roentgenograms or cases representing various phases of a single disease are discussed and opportunity for comment or questions is given, is highly instructive and pleasing to students and should be repeated as often as circumstances will allow. Formal lectures on radiology or allied subjects cannot be dispensed with entirely, but, in the main, the student will profit more greatly from reading standard textbooks and current radiologic literature. To this end the radiologic department should have a special library that is readily accessible during working hours. The informal oral instruction that every student receives from his preceptors every day is perhaps the most impressive and most appreciated didactic feature of his course, because of its objective associations and the chance that it offers for clarifying uncertain points. It is absolutely essential that the student be required to use his reason as well as his memory, to think of the morbid anatomy rather than mere names of diseases, and to arrive at logical conclusions rather than opinions derived from superficial comparisons. But I feel that all didactic methods should be secondary and supplementary to active, closely supervised participation in the work, for the most thorough and most practical knowledge is that which has been tested by personal experience.

Whatever the detailed program of special training may be, the student should not fail to maintain and enlarge his knowledge of other fields of medicine. When he goes out to practice radiology he must not be open to the charge of narrowness so often leveled at all specialists. He should be deeply impressed with the fact that he is to become a consultant in virtually all branches of medicine, not a supertechnician subject to the orders of his colleagues. To meet his responsibility as a consulting physician he must know the diagnostic significance of symptoms, signs and laboratory tests and the efficacy of nonradiologic methods of treatment, as applied to all diseases with which he will deal. Consequently, he should attend meetings of the institutional staff and special lectures by leaders in medicine, note the results of medical or other treatment, and familiarize himself with the principles, applications and effects of various surgical procedures. By this extension of interest he will become far more capable both as radiologist and as counselor.

It may seem that the course I have sketched roughly is too idealistic in certain respects and impracticable to fulfil. But its chief elements are already embodied in courses now offered by some institutions, including my own, and at every school there is room for improvement. At all events, the education of graduate students should have high aims, whether completely attainable or not, and the radiologists of the world can leave no greater or more enduring monument to themselves than pupils whose ability will far surpass that of their teachers and who will add shining achievements to the glory of radiology.

EXPERIENCES IN TEACHING RADIOLOGY TO UNDERGRADUATE STUDENTS

EUGENE P. PENDERGRASS, M.D.

PHILADELPHIA

The teaching of radiology at the University of Pennsylvania School of Medicine could readily be entitled "Physical Diagnosis," "Anatomy," "Physiology" or any of the major specialties in which radiologic methods are employed in teaching. We feel that one of the chief functions of the medical school is training the student to become a good doctor and not a specialist. We have therefore emphasized radiologic methods of teaching wherever they will assist in giving the student a better understanding of his problem.

FIRST YEAR

Anatomy—The class is divided into groups of eight students. Each of these groups receives three fluoroscopic demonstrations, a single demonstration lasting from thirty to forty-five minutes.

The first of these fluoroscopic examinations deals chiefly with the movements of the thorax and diaphragm, associated with respiration, and the heart and great vessels. As the students are the subjects and each one is looked at, a considerable range of variation is available.

At the second fluoroscopic demonstration, the digestive tract is observed. One student takes a barium sulfate meal before going to bed and serves to show the different features about the large intestine. A second student is instructed to come in without breakfast and

is given successively a capsule containing barium sulfate, a barium cookie and a barium meal. The students thus have an opportunity to watch the slow passage of the capsule down the esophagus, noticing those points at which normally there is slight encroachment of outside structures on the lumen of the esophagus and concomitant hesitation of the capsule, likewise, the slow movement of the semisolid cookie down the esophagus, and, finally, the rapid passage of the liquid barium along the esophagus, with its more moderate progress into the stomach. This part of the demonstration is done with the subject in the erect and oblique positions. At each stage, however, the stomach is observed, with the subject in the dorsoventral position. This affords an opportunity to see the shape of the virtually empty stomach and, eventually, of the filled stomach as well. Further, the peristaltic movements of the stomach are watched, also the appearance and behavior of the duodenal cap and the movements of the opaque meal in the jejunum. Following such observations, made by the vertical fluoroscope, the student patient is examined in the horizontal position, both supine and prone, and variations in the shape and position of the stomach and changes in activity are demonstrated.

During the third fluoroscopic period, attention is directed to the various articulations and movements of the joints.

In connection with these fluoroscopic demonstrations, suitable roentgenograms are placed in the dissecting room, so that the students may study, at their leisure, the structures which they have seen by the aid of the fluoroscope. All this work in anatomy is done by Dr. Eliot R. Clark or by members of his staff. We supply whatever roentgenograms Dr. Clark wishes.

SECOND YEAR

Physiology—Dr. Henry C. Bazett and his staff use radiology in teaching students by the demonstration of stomach and intestinal movements in animals. More recently, studies are being made on students themselves, with the observations extended over the morning period of six consecutive days.

Pathology—Dr. Edward B. Krumhaar states he uses radiology in the teaching of pathology, but not so much as he would like to do if there were more time at his disposal. He feels that, in teaching any subject, the important thing is "proportion." Radiology, in this connection, is taught by Dr. Philip J. Hodes, of the Department of Radiology. He tells the students what radiology contributes in the diagnosis of the various pathologic lesions, with demonstration of illustrative films. These correlated expositions are presented before the class sections receiving instruction in gross morbid pathology.

THIRD YEAR

Applied Anatomy—This subject is taught by Dr. Oscar V. Batson. Every one is familiar with Dr. Batson's enthusiasm about the necessity of using radiologic methods in the teaching of anatomy. There is constant reference to roentgenograms in the work on the chest, with emphasis on the differences between the anatomy of the dissecting laboratory and the anatomy of the living thorax. In considering the heart, Dr. Batson has had the good fortune to show the students Dr. George Levene's movie film of cardiac movements in health and disease. Roentgenograms are used also for studying the distribution and rearrangement of various struc-

tures, which may be so investigated because of their x-ray opacity or their ability to be injected with a radiopaque medium. Dr. Batson is interested eventually in developing more demonstration material, converting the three dimensional anatomy into shadow anatomy and then into roentgenograms.

Didactic Lectures—The entire third year class is given an elementary course in radiology, consisting of sixteen hours. Holmes and Ruggles' "Roentgen Interpretation" is used as a textbook. X-ray tubes and fluoroscopic screens are shown to the students and brief explanations given concerning their operation and control. No effort is made to go into the physics of the x-rays, on the assumption that the student has had training in this subject during his premedical days. Dangers in connection with radiology and methods of protection are stressed. A short discussion of the medico-legal aspect of radiology is presented. Further than this, an attempt is made to teach the students to value both the potentialities and the limitations of the roentgen examination, as well as those conditions in which its use is essential. Emphasis is placed on the correlation of clinical and roentgen observations rather than presenting a tremendous number of slides of various pathologic conditions. For instance, the student is shown films, or slides, of the chest of a patient who has no pathologic process in the heart or lungs. The films are arranged to demonstrate the effect of posture on the domes of the diaphragm and the cardiac silhouette, and how, in turn, these structures may modify the physical observations, such as percussion and auscultation. After this the student is shown roentgenograms of a pleural effusion. Films exposed with the patient in various postures are presented to demonstrate how position affects the shadow cast by the pleural effusion. Such a presentation serves to focus the student's attention on physical diagnosis rather than on roentgen diagnosis. The entire field of diagnosis is covered in this manner.

During this course of lectures, five students are selected each week to occupy the front row seats and, in order to emphasize certain points, questions are asked. To stimulate further interest on the student's part, questions and discussion are encouraged, and often at the end of the hour, or perhaps later by postal card, different problems are brought up. Such inquiries are answered at the beginning of the next lecture hour.

In addition to the foregoing, a few lectures are given on roentgen and radium therapy. Here again the fundamental principles of the effects of irradiation on various tissues are stressed, rather than an outline being given of technic of therapy in the different conditions in which its use is indicated. I believe that such an approach as this, in presenting the subject of radiology, is rational and, possibly, an obligation.

The third year students at Pennsylvania do not have ward work but are assigned as student physicians to the outpatient department. There is usually so much clinical detail, however, that little time is available for the instructors to show the students the roentgenograms made on their patients. Occasionally a student, interested in an unusual patient, will come to the radiologic department for demonstration and explanation of the roentgen observations by some one in the department.

At the end of the year a final examination is given on the course. The questions asked are general and of a type with which the general practitioner should be conversant.

FOURTH YEAR

During the fourth year the students become clinical clerks in the hospital wards. Each student receives at least forty hours of instruction. The general approach to the radiologic teaching is a correlation of the clinical and the roentgenologic observations on patients seen by these students in the wards of the hospital. The teaching is divided into the following groups: medical, pediatric, general surgery, urology and neurosurgery.

Those students in the medical section attend a radiologic and clinical conference once a week. An hour is devoted to the presentation of the case history, the physical and roentgen observations and a discussion of diagnostic possibilities or therapeutic approach. The discussion is led by the radiologist, chiefly in the form of questions, which are considered by the various ward chiefs in medicine. In addition, the medical staff holds a seminar with the students for two hours each week. This may be attended by the radiologist whenever cases are presented which need radiologic explanation. Various members of the medical staff hold a "sun parlor" conference once a week too, at which films of interesting cases are presented to students as a part of the clinical record.

A radiologic-pediatric conference is attended by the chief of the department of pediatrics, interns and students. This group meets once a week for one hour. All cases that have undergone a roentgen examination are reviewed clinically and the films presented. Since the majority of the cases comprise an examination of the chest, the student has an excellent opportunity to check his physical observations with regard to the nature and size of the lesion which may be present. This session is sometimes devoted to a brief discussion of pathologic changes in long bones in relation to the roentgen examination. Occasionally a student or an intern may present a brief review of some subject, such as obstruction in the respiratory passages, in conjunction with current cases showing this type of lesion.

Radiologic aids in surgical diagnosis and treatment are presented at a weekly one hour conference attended by surgical staff members, students and a member of the radiologic staff. This has been divided into general surgery, urology and neurosurgery. In the former group, students are required to present a brief abstract of the clinical history and physical examination concerning current cases in the wards of the hospital. The films are presented and the cases discussed clinically by some member of the staff. It has been our purpose during this session to present all current patients who have had a roentgenologic examination, whether the result of the examination has been positive or negative. Such a procedure helps the student by indicating when a radiologic examination can be of assistance, and also the type of examination to be considered. Frequently two or more cases may be available which are more or less similar clinically. At such times the greater part of the hour is devoted to a discussion of one general subject, such as lung abscess, intestinal obstruction or gallbladder disease. In order to illustrate salient points, particularly with regard to surgical diagnosis, other films in our teaching records are presented. In general, controversial details are avoided, that the student may not be confused.

The roentgen diagnosis of urologic conditions has been presented in a more didactic way, on account of (1) the special nature of the examination, (2) the unfamiliarity of the average student with observations

by intravenous or retrograde pyelography and (3) the lack of a proper selection of current cases. We have therefore attempted to present in one or two hours the normal appearances and variations that may occur. This is followed by diagnostic points concerned with urinary calculi, tumors, stone, and anomalies. Very little time is offered for open discussion, but questions by the students are encouraged during the conference.

In neurosurgical diagnoses we have used much the same procedure as in urologic teaching. Because of the unfamiliarity of the student with roentgen examinations of the skull, it has been necessary to review roentgen anatomy and point out the landmarks that most frequently aid in diagnosis. We present indications and contraindications for encephalography and ventriculography, the normal encephalogram, followed by illustrative cases to show cortical changes, such as atrophy or arachnitis, scars or tumors, the normal ventriculogram, followed by films of patients which show characteristic deformities associated with the more frequent mass lesions in the frontal, parietal, temporal or occipital areas.

A member of the radiologic staff is present at the neurosurgical conference, one hour each week. Selected cases are presented to the students and the films of these cases discussed by the radiologist as a part of the clinical evidence.

This year we have extended our teaching of the students on the surgical trimester to include ward rounds, one hour each week, pathologic conferences, two hours every fifth week, and elective tumor conferences, one hour each week. As each section in surgery changes every five weeks, the students in these sections have four hours of ward rounds, two hours of pathologic conferences and an elective five hours of tumor conferences.

Ward Rounds—During the first hour, the students are brought into the Department of Radiology and shown various equipment used in radiation therapy. As each piece of apparatus is demonstrated, the students are shown how it is actually used. It is our feeling that each student should be familiar with some of the more important terms that are employed in radiation therapy, in order that he may know their meaning when reading current literature or when consulting with a radiologist.

The discussions during each of the remaining three ward round periods depends largely on the patients in the hospital who are receiving irradiation for infection or a malignant condition. Regardless of the type of malignancy under consideration, the approach to the problem and its discussion are approximately the same. But little time is spent on the usual diagnostic appearances in a late carcinoma. Most of our energies are directed to the signs indicative of the early lesions. Naturally, this involves discussion of procedures such as biopsy, Wassermann tests, and roentgen therapy as a therapeutic test. After the diagnosis is made, the treatment of the tumor in question is discussed. We do not immediately state that this or that is the treatment of choice. On the other hand, we try to promote discussion of all possible methods for treatment of tumors, arguing pro and con, until finally the students themselves reach what they think is the method of choice. In this connection the students are shown irradiation reactions and effects, and the methods employed in their care.

In actual practice, the procedure we follow is this

1 The history and physical examination of the patient are given by the clinical clerk

2 We then choose a student not familiar with the case to discuss the differential diagnosis. If his discussion is not complete, we designate the role of consulting physician to another student, whose job it is to agree or perhaps to bring up another possibility. If the diagnosis is still unrecognized, each member of the group expresses an opinion

3 Another student then acts as the family physician, telling how he would finally prove his diagnosis. If he is not entirely satisfied, he chooses another member of the group as a consultant. If the discussion of these students is incomplete, the entire group is again asked for opinions

4 After the diagnosis has been decided, another student acts as the family physician and is asked to treat the patient. If this student's therapeutic methods are not inclusive enough, we again assign the role of consultant to another student, who may act as the radiologist and, when necessary, we add still a third, who may act as the surgeon. With this plan we approach the problem in a practical manner

Pathologic Conferences—Sometimes there is nothing of tumor interest in these sessions. On other occasions the department of radiology is asked to explain why a certain type of treatment was carried out for a specific tumor removed at autopsy. At such times the rationale and arguments for the type of therapy used in the case are fully discussed

Tumor Conferences (elective)—During the first portion of these conferences, patients with unusual tumors are shown. During these demonstrations the type of pathologic process and therapeutic measures are discussed. At other times the end result of a therapeutic procedure is demonstrated in order to illustrate what can be expected in the treatment of certain malignant conditions. The last half of the hour is turned over to a member of one of the specialties, such as a gynecologist or an otolaryngologist, who discusses the most recent advances in a particular type of malignant growth which he, as a specialist, has been called on to treat or about which he has been invited to act as a consultant

Some of the fourth year students do not receive all their training in the University Hospital but are assigned to other hospitals for their clinical clerkships. Dr. M. Lowry Allen at the Episcopal Hospital, Dr. Paul Bishop at the Pennsylvania Hospital and Dr. Herman Ostrum at the Philadelphia General Hospital give clinico-radiologic conferences on diagnosis similar to that described with slight modifications arranged according to the teaching schedule of these various hospitals. The only major difference in the teaching is that there is less effort made to develop the therapeutic aspect of radiology

At the end of each trimester, an examination is given. This usually consists of two questions, based on the subjects considered in the conferences. In addition, one question is given in the final written examination

CONCLUSION

I should like to state, very humbly, that I know but little concerning the teaching of radiology. We are constantly changing our approach to this problem after

careful consideration of its many phases with our medical and surgical friends. If we fail in our efforts, we have only ourselves to criticize, as our association with the entire staff, in the preclinical and clinical years, has been most cordial and stimulating

3400 Spruce Street

UNDERGRADUATE TEACHING OF RADIOLOGY IN THE MEDICAL SCHOOLS OF THE UNITED STATES

A SURVEY

CLAUDE MOORE, M.D.

WASHINGTON, D. C.

Since radiology is the newest major branch of the practice of medicine, there is considerable difference of opinion among the entire medical profession as to its value in the diagnosis and treatment of disease. The medical schools of the United States also place different degrees of importance on this specialty. To determine the status of the teaching of radiology, a survey was made by review of all the catalogues of all the medical schools in the United States giving a full four year course and rated as grade A by the Council on Medical Education and Hospitals of the American Medical Association. Since the medical schools could not all be visited, this had to be done entirely by the last available catalogue published by each medical school. The information secured from these catalogues was checked with the information furnished by the last Educational Number of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*¹ and the latest list of the Diplomates of the American Board of Radiology.²

There are sixty-eight class A medical schools giving at least a full four year course and an M.D. degree. Some of them have no connection with universities and some of them have but limited or no connection with large hospitals.

An attempt was made to determine both the quality and the quantity of teaching that was offered as well as the importance of this specialty in each school. Forty of the medical schools had a separate radiologic department organized under a separate head and equal in rank with the other departments in the school. One medical school makes no effort to give any instruction whatever in any branch of radiology. Its latest catalogue merely states, in a paragraph under medicine, "324 Radiology and Radiotherapy (Elective), one hour a week. The staff." The catalogue makes no mention of any staff in radiology. The other twenty-seven medical schools mention or list the teaching of radiology as a division or a part of some other department. Another school has only one statement to make with regard to radiology. This is under the department of surgery and says "This course embraces the principles of operative surgery, x-ray and anesthesia." The instructor of this course is listed as Associate Professor of Surgery (Roentgen). By far the majority of these twenty-seven classifications are under medicine or surgery, but some of them are mentioned under pathology,

Read before the Section on Radiology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1937.

¹ Medical Education in the United States and Canada. J. A. M. A. 107: 661-715 (Aug. 29) 1936.

² Diplomates of the American Board of Radiology. Am. J. Roentgenol. 31: 116-123 (Jan.) 1937.

therapeutics, dermatology and anatomy, the reason for this apparently being that professors in these subjects teach their specialty in connection with radiology or that they are radiologists to affiliated hospitals. The variety of information given in the catalogue is even greater than would be suspected. Some devote a page or more to describing the course in radiology, while other catalogues have only a sentence or two.

The size and the rank of the staffs in radiology are even more variable than the amount of space describing radiology in the catalogues. Thirty-six medical schools give the rank of full professor to one or more mem-

TABLE 1—*Extent of Instruction in Radiology Listed in Medical School Catalogues*

68 class A medical schools in the United States give a four year under graduate medical course
40 schools have a separate radiologic department
27 schools list radiology under some other division
1 school does not list any radiologic course of instruction or mention any radiologic faculty
36 schools give one or more members of the radiologic faculty the rank of a full professor
2 list the highest rank as instructor in radiology

bers of the faculty in their departments of radiology. In two schools the title of Instructor in Radiology is the highest rank given to the member of the faculty teaching this subject. The other thirty-four schools list the faculty members under all the various classifications common to university rank below that of full professor. Several schools, even among those giving the rank of full professor, add in parenthesis following the title the words "radiology or roentgenology." It is impossible to tell whether this faculty member does teaching other than in radiology or whether the title of "professor of radiology" is not of sufficient dignity or value to be listed as such. The size of the staffs of the radiologic departments of the different medical schools vary all the way from one to ten members. Several schools, particularly those giving instruction in all four years of the medical course, have large, well organized staffs, with different members teaching special subjects in this field. In some of the large university medical schools the department of physics and experimental biology is closely affiliated with the radiologic staff. A few schools seem to allow the teaching of radiology by sufferance. One large university medical school with exceptional hospital affiliations has eleven instructors of surgery and eleven instructors in medicine of professorial rank and only one associate professor of roentgenology. Another medical school, already mentioned, has eighteen members of the surgical and medical staff ranking as professors, and the sole member of the radiologic staff is listed as instructor in roentgenology. The one medical school mentioned as not giving any course has no mention whatever of any radiologic staff or even of an instructor teaching radiology. As would be suspected, the larger faculties are in the medical schools of the largest universities connected with prominent hospitals. The ability of the faculty can be judged only by the professional connections of its members. The only information available was the latest list of the diplomates of the American Board of Radiology.² In six of the medical schools no member of the faculty was a diplomate of this board. Either they had not applied to the board, their acceptance had been postponed, or they had been turned down as ineligible or inefficient.

According to the American Board of Radiology, twelve medical schools do not have staffs sufficiently well trained to use radium in the treatment of disease. This is said because the radiologic faculties of these medical schools are listed by the board as proficient only in roentgenology. In checking the faculty roster of all the medical schools it is interesting to note the number of higher ranking members who are not diplomates of the American Board of Radiology. Many of their junior associates have satisfied the board that they are proficient in radiology. One radiologic department of a medical school in a large city, with four professors and four associates or instructors, had no member of the faculty who was a diplomate of the American Board of Radiology. In some other schools it is only the junior members of the radiologic staff that are diplomates of this board. These young men appreciate the value of this membership in the future upbuilding of radiology in the United States.

It is almost impossible to judge, with any degree of accuracy from the catalogues, the amount of radiologic instruction given medical students by the medical schools. Seven medical schools teach radiology in all four undergraduate years. Five more schools have courses in three different years. The other medical schools are about equally divided in number as to instruction in one or two years. Five medical schools make the course in radiology entirely elective. All others say they require some definite amount of instruction. The number of hours is very indefinitely stated or is so mixed up with other courses that no fair idea of the amount of instruction could be determined. The general average of all schools would probably be between twenty and fifty hours for all courses, both didactic and clinical. Several medical schools offer opportunities for senior students to be clinical clerks in the radiologic departments or affiliated hospitals, while another school offers an elective course for seniors to become proficient in roentgenologic technic.

All sixty-eight medical schools were checked with the latest roster of hospitals giving a residency in radiology.

TABLE 2—*Qualifications of Instructors in Radiology and Affiliation with Hospitals*

6 schools have no member of the faculty who is a diplomate of the American Board of Radiology
12 schools have no member of their faculty who is fully qualified to teach radium
7 schools teach radiology in four undergraduate years
5 additional schools teach radiology in three of the four undergraduate years
32 schools are not affiliated with hospitals giving a residency in radiology credited by the Council on Medical Education and Hospitals of the A. M. A.
36 schools do have these hospital connections

accepted by the Council on Medical Education and Hospitals.² Thirty-two medical schools have no connections with these hospitals, leaving thirty-six that are affiliated. It was felt that, when a medical school has connections with a hospital radiologic department giving a residency in radiology, both the quality and the quantity of instruction available to students would be superior to those schools having no such connection. Usually the chiefs of the radiologic department of these hospitals are men of national or international reputation and they are sufficiently interested in the future development of radiology to see that the student become as well acquainted as possible with this specialty.

It is hoped that this discussion and information, secured only through the catalogues prepared by the medical schools, will encourage the Council on Medical Education and Hospitals to make and publish a direct survey on the undergraduate teaching of radiology

1801 Eye Street NW

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs KIRKJIN, PENDERGRASS AND MOORE

DR MERRILL C. SOSMAN, Boston There are two separate problems in this symposium which should be discussed. Let us take up undergraduate teaching first. Every one realizes that any subject can be taught from a dozen different points of view. Anatomy, for example, can be taught from the point of view of morphology, of biology, of physiology or function, or from a purely roentgenologic point of view. Similarly, all of medicine can be taught, and taught well from widely divergent points of view. For example the approach may be through etiology, through pathology, through therapeutic channels or, again, through roentgenology. In undergraduate teaching, however, it is important to teach not radiology but anatomy or pathology from the radiologic point of view, an attempt being made to give the student the necessary information from another and different aspect and thus help him to correlate and consolidate his knowledge. In graduate teaching, an attempt should be made to impart to students not just the facts of radiology, considering it as a trade or as a laboratory procedure but rather from the clinical point of view, and teach its limitations as well as its specific and positive values. In this way the teacher should attempt to turn out roentgenologic clinicians who, with experience, may become really consultants rather than the all too prevalent reader-of films type. Two points in the graduate teaching of radiology, which I consider the most important of all, may be emphasized. 1 For the student of radiology, the most important thing is to choose, if he can, the man under whom he takes his work and who gives him the attitude of mind and the mental stimulus which is so much more important than the acquisition of facts. The man is the important thing, not the place or the course of work, however complete and attractive it may seem. 2 For the teacher of radiology, the one thing of utmost importance is not the detail and the order of the work to be given or the type and amount of instruction, but rather the careful selection of the candidate. I feel that the choice of the proper man to be trained far outweighs the thoroughness of his training, provided the opportunity to acquire knowledge is available and the candidate has the character to profit by the acceptance of responsibility in the department to which he is assigned.

DR J. H. J. UPHAM, Columbus, Ohio Dr Moore presents rather a chaotic condition of affairs in his survey. This is largely a reflection of the general situation of medical colleges with regard to the teaching of specialties all along the line. The rapid growth of medical knowledge in general and the special fields in particular has led to demands on the present college curriculum that are difficult to meet. There is danger of overcrowding, if that has not already occurred. As a dean of a medical college, I am continually under pressure from this or that specialty for more teaching time. Not infrequently a dominating personality in some college will bring about a greater emphasis on his specialty. There is great necessity for a general understanding and evaluation of the needs of the prospective practitioner in considering the places in the curriculum of all the specialties. There is scarcely a field of medicine in which radiology does not enter in some degree so that it must have an important place in undergraduate instruction. The teaching of this subject therefore embraces two concepts: first, as it affects the prospective practitioner and second as it looks toward a prospective specialist. In my opinion the latter enters into undergraduate instruction only as do the other specialties. That is a teaching of basic principles with the idea that should the student expect to enter this or that specialty he will have to take extensive postgraduate instruction. I believe, therefore, that the teaching of technic should be little more than brief basic instruction of a very general character, so that the principles may be gained with a knowledge of the dangers of

attempting to practice them without thorough postgraduate training that most of the instruction be along the lines of the value of radiology in the various fields of medicine and the need of proper interpretation of films. That the teachers of this subject should be thoroughly qualified goes without saying, and their titles should be commensurate with the importance of the subject. Such instructors would be able to recognize those students who are particularly qualified or have a flair to practice radiology and, by electives, prepare them for later development. The outline of instruction in the University of Pennsylvania given by Dr Pendergrass follows my own ideals very closely. I feel however, throughout that the emphasis should be on the illustration of the definite uses of radiology in medicine, the need often of radiologic consultation, and that the impression should not be given too easily that on the basis of even this quite thorough instruction the graduate is prepared without further training always to read films properly and certainly without extensive further training that he is prepared to practice radiology. Dr Kirklin's paper suggests a high plane of postgraduate training and one that appears excellent.

DR FRED J. HODGES, Ann Arbor, Mich. As a teacher it has been encouraging to me to learn that the difficulties encountered in our institution are closely paralleled by the experiences of others. Dr Moore has drawn attention to the striking lack of uniformity among medical schools in the matter of presenting the subject of radiology to undergraduate students. At the University of Michigan the faculty of medicine has recently begun revision of its curriculum to correct generalized overloading due to the addition of new subject matter over a considerable period of years. We find that decisions regarding the proper allocation of teaching time are difficult to reach not only in radiology but in all divisions of medicine. The teaching plan for undergraduate students outlined by Dr Pendergrass corresponds closely to ours. We too attempt to place primary emphasis on the purely medical rather than the technical aspects of radiology. The required hours of instruction are nearly identical. I am in complete agreement with all the previous speakers regarding the scope and the ultimate aim of graduate teaching in this subject. Dr Kirklin's plan is excellent both in theory and in practice. Ideals of graduate training in radiology as expressed by Dr Holmes are exceedingly important if our subject is to deserve high ranking in the field of medical education. The necessity for accommodating student instruction to the time consuming activities of a busy clinical practice is a real problem, to be solved only by careful budgeting of time and the maintenance of a sufficiently large staff.

DR THOMAS A. GROOVER, Washington, D. C. I wish the authors would state in closing the discussion whether the present-day facilities for postgraduate study are adequate. A good deal has been said about the radiologist choosing a student, but something can be said, on the other hand, about the student choosing his instructor.

DR ROSS GOLDEN, New York. I agree with Dr Sosman that the choosing of the man is of prime importance. I went on record two or three years ago to the effect that I believe a man should be given a point of view in radiology before he spends his year in the fundamental medical sciences. We have tried that now for two years at the Presbyterian Hospital in New York. The first man who went through began his service October 1 and spent ten months in the diagnostic department and then went into the department of pathology, where he took part in the teaching, and then in the department of surgical pathology and then had his course in physics. Then he came back and went in the radiotherapy division. The second man who came through spent six months in the diagnostic division and then four months in the radiotherapy division. This spring when plans for the third man to take the three year service came up for discussion, the question was raised as to whether he should have some radiotherapy before he went into the year of fundamental sciences. On consultation with the two previous men, he decided that he would like to have some radiotherapy first. The first man felt that he would have understood the pathology of radiotherapy better had he understood the technic, and the second man felt that he was helped very definitely by having had some practical experience in radiotherapy. Based on my own reaction I feel that a point of view would be of definite help in enabling the men to get the most out of the

year in the fundamental sciences I know that there are well informed people who think that this is of minor importance, but it has seemed to work out well as we have tried it in the past two years

DR CHARLES L. MARTIN, Dallas, Texas I believe with Dr Pendergrass that every effort should be made to develop undergraduate medical students into good doctors This can be accomplished in many instances by combining some of the subjects now taught separately At the Baylor University Medical School the prescribed course in radiology deals only with diagnosis, while radiation therapy is included in a required course on tumors The active staff of the Baylor Tumor Clinic holds one exercise each week for the senior class The pathology, diagnosis, treatment and prognosis of tumors are discussed and actual patients are shown before, during and after treatment The director arranges the clinics in advance, so that each one deals with a different type of pathology, and since fourteen men take part in the presentation, they represent a consensus of opinion The radiation therapist has a very important role in this type of teaching and I feel that our students know a great deal about the proper care of patients with malignant growths by the end of the year In my opinion this is much more important than the elaboration of the physical data so often included in a course in radiation therapy for undergraduates

DR EDWARD L. JENKINSON, Chicago I believe that the selection of the student, the candidate, especially in graduate work, is most important I think a good man will be a good man in practically any well regulated department When the men that I have had come before the board, I think it is easy to tell how well they are going to do by what they have done during their training period in the department So I think the selection of the candidate is most important During the formation of the curriculum, for instance, the orthopedist who on certain days has his lectures on bone conditions could take, say, forty-five minutes of the hour in teaching or giving to the student the orthopedist's side of the question, and the last fifteen minutes could be taken by the radiologist, who could give the student the important x-ray appearances of the disease under discussion I think the same plan could be used in gastro-intestinal medicine It certainly could be worked in in heart conditions and practically all the medical subjects I believe in this way one could bring the students in closer contact with radiology as it applies to medicine

DR CLAUDE MOORE, Washington, D. C. It is unfortunate that more men of lesser prominence have not discussed this symposium While attending this meeting I have had the opportunity to discuss the undergraduate teaching of radiology with a number of radiologists from smaller cities and towns who have come in contact with recent medical graduates who were not associated with larger hospitals and clinics in their undergraduate work I have been surprised to find the amount of ignorance these radiologists report among these young physicians One radiologist told me this morning that last week he talked with a young physician who had been out of medical school for two years and did not know that duodenal ulcers could be found by means of the roentgen ray It is surprising the lack of knowledge of radiology among graduates of the more isolated medical schools not connected with large clinical facilities It seems that this is not the fault of the radiologists of the country but is the fault of the administrators of the medical schools This statement is confirmed and illustrated by the amount of time given by radiologists to medical schools, receiving in return, in many cases, a low university rank, and working in competition with a half dozen full professors in other branches of no greater importance than radiology These radiologists are willing to give their time and interest to promote their specialty, with little or no personal reward

DR B. R. KIRKLIN, Rochester, Minn. Dr Groover asked the question whether or not the facilities for training a sufficient number of radiologists are adequate The other essayists have left that question unanswered, so I will attempt to answer it to the best of my ability by saying that I do not think the facilities are adequate at the present time We hope, however, that it will be only a matter of a short time until this deficiency is overcome It has been pointed out that it is necessary to provide for a fairly large replacement to supply the normal

demand for radiologists, not taking into consideration the increased demand by clinicians for radiologic service. I would also state that the American Board of Radiology is now attempting to classify and to list those institutions or individuals who have what we consider to be adequate facilities for giving the type of radiologic training that should be given Dr Sosman is chairman of that committee, and I am sure he will shortly have a satisfactory report

TEACHING UROLOGY TO MEDICAL STUDENTS

ROGER W. BARNES, M.D.

LOS ANGELES

The recognition of urogenital disease and its proper management are dependent to a large extent on the general practitioner, and the mental equipment he uses is, in turn, dependent to some extent on his training in medical school This is especially true with the recent graduate, and the more practical and vivid his undergraduate teaching has been made, the more mental equipment he will have to cope with the daily problems of his practice

A review of the bulletins of twenty-two representative medical schools reveals a wide variation in the assignment of time to the teaching of urogenital dis

TABLE 1—Assignment of Hours to Teaching Urogenital Diseases in Twenty-Two Medical Schools

	Schools	
	Number	Percentage
No urology listed	1	4.5
Elective only	2	9.0
No didactic course listed	5	22.5
From 8 to 20 hours of didactic instruction	7	31.5
More than 20 hours of didactic instruction	10	45.0
No clinical course listed	6	27.0
Clinical required hours not given	4	18.0
From 10 to 20 hours of clinical teaching	3	13.5
More than 20 hours of clinical teaching	7	31.5

eases This ranged from a minimum of no time allotted for this course to a maximum of 110 hours Table 1 gives a summary of this review

In view of the present trend toward more clinical teaching and less didactic instruction, it is surprising to note that eight, or 36 per cent, of these schools list no clinical course in urology Of those schools listing clinical hours, the minimum is sixteen and the maximum fifty-nine, with an average of thirty-one Five schools, or 22.5 per cent, listed no didactic course Of the schools listing didactic hours, the minimum is eight and the maximum fifty-seven, with an average of twenty-three Three schools listed no required course in urology, and of those requiring a course the minimum total hours is sixteen and the maximum 110 with an average of forty-eight

Since medical students are taught to be general practitioners, it would seem that the number of hours for each specialty taught in the medical course should be in the same proportion to the total as that specialty is to the total of the practice of the general practitioner In order to determine this, a questionnaire was sent to 120 physicians in general practice A compilation of seventy-eight that were returned showed that an average of 8 per cent of their practice was urogenital in nature

From the Department of Surgery (Urology) College of Medical Evangelists
Read before the Section on Urology at the Eighty Eighth A. M. A. Session of the American Medical Association Atlantic City, N. J., June 11, 1937

The minimum was one-third per cent and the maximum 50 per cent. As there are approximately 2,500 total hours in the clinical division of the medical course, 200 hours, or 8 per cent, would be devoted to the teaching of urogenital diseases if this proportion were carried out. These figures are of course only a rough estimate at best, but they do show that the time devoted to the teaching of this subject is not too much in proportion to the entire course.

There has been a growing tendency to shorten the courses in the specialties and in some instances to have them taught by general men rather than specialists. It is impossible to cover more than a small part of the subject of urology when teaching medical students, but it is a mistake to shorten this course to such an extent that the essentials necessary to equip the general practitioner properly are inadequate. Even though teaching the more complicated urologic procedures is not attempted, still the urologist is the most suitable person to teach this specialty. As Boyd¹ has stated, the general practitioner does not have sufficient interest in the specialty and has had neither the training nor the experience necessary to present to the student properly the essentials of the management of urogenital diseases. A few urologists have sufficient pedagogic background or the natural ability to lecture so that the students can grasp and retain what is taught. Most instructors are not so endowed, however, and it is necessary to resort to other methods of teaching. The best solution to the problem is by case teaching, i. e., by having the student care for the patient himself, take the history, make the examination and prescribe and give the treatment. He must of course be supervised at each step and told of the mistakes he makes and of the way to avoid them.

Even in the largest clinics it is not always possible to have patients available with whom to demonstrate each disease as it is taught to the student. This is especially true in the smaller clinics, and for this reason it is necessary to supplement the case study and patient demonstration by other means of visual instruction. Lantern slides, motion pictures, drawings and models can be utilized in such a way that they can be made a very valuable adjunct to teaching and in fact are in many ways superior to the patient himself as a teaching aid. For example, a carcinoma of the penis or even a genital ulcer might not be available during the time a

The necessity for a careful history and physical examination is axiomatic, and these, together with the more simple diagnostic procedures, laboratory tests and routine treatments, should be emphasized. Palpating and massaging prostates, passing catheters and sounds, treating gonorrhea and giving bladder irrigations are the things the student will do when he becomes a general practitioner, and these are the things he should be taught while in training. In every school there will be found students who think it is a waste of their time to repeat these and who believe they have mastered them.

TABLE 3—Urogenital Diseases in General Practice

Returned Questionnaires Tabulated	Proportion of Practice Urogenital in Nature		
	Minimum	Maximum	Average
	78	50%	8%

after seeing them done or after doing them only once or twice. The instructor should endeavor to change this attitude by impressing the value to the student himself of thoroughly mastering these routine procedures and to show him that when he is out in practice these are the things he will want to know more than anything else. To teach cystoscopy and surgical technic to the medical student in the short time allotted for the course in urology is almost impossible, and these procedures should be reserved for graduate teaching.

947 West Eighth Street

ABSTRACT OF DISCUSSION

DR. GEORGE F. CAHILL, New York. The review of the assignment of time to the teaching of urologic diseases in our medical schools undertaken by Dr. Barnes is most timely. Urology apparently does not occupy sufficient time in most schools to supply the needs of students for its proper understanding. Most urologists agree that the teaching of the more complicated urologic procedure is not to be attempted within an undergraduate curriculum but properly belongs to graduate teaching, and that only the essentials for a proper understanding of the main pathologic, diagnostic and therapeutic procedures can be covered in the time that at present is allowed in the medical schools. It is, however, possible to present in the basic courses in the early years didactic lectures or teaching linking these departments with the specialties. These urologic lectures or demonstrations in embryology and anatomy and pathology should be given by the urologist. He best can give the point of view which is later to be developed as essential for the understanding and proper appreciation of the specialty. Modern teaching in medicine has slowly evolved clinical case teaching. Such teaching has evolved the clinical clerkship. Most medical schools have clinical clerkships in the four major courses: medicine, surgery, obstetrics with gynecology and pediatrics. Such clerkships should include urology. We feel that the student can secure a proper understanding of what the specialty covers only by a concentration of his time within the specialty, if possible for the whole day, with instruction by the residents and the necessary didactic or illustrated case teaching, even though the entire teaching time covers only two weeks. The complicated urologic procedures developed during the last twenty years have gone far beyond the attempt to teach complete familiarity with these to the undergraduate and belong properly in postgraduate work. Dr. Barnes is to be complimented for giving us this graphic, basic idea of how to examine a patient urologically, and I am pleased to see a combination of teaching with demonstration as evinced by the sound movies.

DR. NELSE F. OCKERBLAD, Kansas City, Mo. The author's presentation of this subject is excellent and timely, and the motion picture was excellent. No one knows how much work it takes to make such a picture unless one has tried it. The teaching problem is the same everywhere. Teachers are largely

TABLE 2—Number of Hours Scheduled for Course in Urogenital Diseases in Twenty-Two Medical Schools

Clinical Hours			Didactic Hours			Total Hours		
Min	Max	Aver	Min	Max	Aver	Min	Max	Aver

group of students is taking the clinical work in urology, but if these conditions are shown in a slide, or preferably in a motion picture in color, the student will make a mental picture which will be much more lasting than if a word description were given. A carcinoma of the prostate may not be available, but if the student can feel a model of this condition and take as long as he wishes without the fear of causing pain or inconvenience to the patient, he will receive a much deeper and more lasting impression than if he were given a word description of how such a prostate felt or were allowed a hasty feel of such a prostate in a patient.

¹ Boyd M. L. Teaching Urology to Medical Students. J. A. Am. N. Col. G. 278 (Sept.) 1931.

born, not made. The best reference books on urology are too expensive and too extensive. I have tried to get around this with a mimeographed manual or outline. The exhibit of Dr Barnes dealing with the prostate is extremely ingenious and ought to be helpful to the medical student who has just broken into a new world when he first comes to the dispensary.

DR. R M LE COMTE, Washington, D C. Dr Barnes has shown how little time is given to teaching this rather complex subject. Judging from my own experience his figures particularly regarding clinical instruction, exaggerate rather than understate the actual time put in on the subject. It is important to remember that only a few of the undergraduates will ever practice urology intensively and that we should limit our efforts to giving them sufficient knowledge and skill to make rather safe general practitioners who are able to recognize genito-urinary diseases clinically and to establish a diagnosis and carry out treatment which requires a procedure that is not very complex and technical. If we try to do more than this we are very apt to cloud the issue rather than clear it. At Georgetown University the students work both in the dispensary of the University Hospital and in other hospitals, and also in the wards, giving as much time as practicable, but just as both Dr Ockerblad and Dr Barnes have said, the material is often either not available in sufficient amount or not the proper type at the proper time. In addition, we give thirty hours' didactic teaching each year. We stress the symptoms and the medical treatment. In considering the various organs, diseases are arranged in a systematic way according to the etiology and pathology. We believe that if this is understood the symptoms, diagnosis and treatment will be more readily comprehensible and more impressed on the mind. This is done mostly by quiz work, sections of the book are assigned for study and the students are then quizzed on the material. We find we have to vary the method not only with the different classes but in some instances with the different sections of each class. We have no way of measuring our results very accurately. In some instances we feel rather proud, notably when a recent intern was able to make a diagnosis of perinephric abscess which puzzled members of the medical and surgical staff both of our own hospital and of others. We were rather chagrined, however, when, day before yesterday, a man came in with acute gonorrhea and I found one of my students who had graduated less than five years ago had been treating his total acute posterior urethritis by autohemotherapy for three weeks.

DR N G ALCOCK, Iowa City. I believe that this is the first paper dealing with the subject of teaching urology that I have heard presented in this section in fourteen years. It is a timely and important subject to come before the group. It is not so much a question as to how much time in hours is to be given to the teaching of urology as it is a question of how economically those hours can be used. In filling teaching posts in medical schools I am of the opinion that efficiency in the use of the students' time is not always a determining factor in the selection of the teacher and I am quite sure that the teachers are frequently and quite commonly selected on the basis of how many papers they have written and on how well they are known to the profession and of what advertising value they may be to the particular school with which they are affiliated. The demonstration by Dr Barnes gave a good illustration of economy in time in teaching. His moving picture took, I think, about seven minutes. There was nothing particularly new in the subject matter he presented and the physicians in the audience probably learned nothing from it, but to the student who has no background for evaluation of signs and symptoms and information it would be very enlightening. The ordinary student in watching the moving picture of the urethra through which he was passing a catheter would learn more in the three minutes it was on the screen than he would in three hours of didactic teaching. That is the thing which counts. In our medical education discussions we are talking a great deal about the number of hours to be devoted to a subject and what will be taught, but very little, if anything is said as to how it shall be taught. There are two primary qualifications that any good teacher should possess. He should be able to transmit information, to analyze the subject matter and to select only those things which are vital for the student

to know and then to drive those things home. If he will analyze his material and pick out those important points, 50 per cent of his students should pass his course with a grade of at least B. Good teachers are the ones who give many high grades and fail very few students. The other qualification that the good teacher should have, and this is the great one, is the ability to stimulate the student. It is the divine spark in the teacher that will light up the fire in the student. It is something that is born in one and that one can never acquire. If a teacher does not have it he will never be a great teacher. If he does have it, it does not make much difference how he teaches, he will be a great teacher.

DR ROGER W BARNES, Los Angeles. I wish to thank the discussants. I agree with them that we should spend more time in this section on methods of teaching urology to both undergraduate and graduate students.

A SPECIFIC FEBRILE REACTION TO SULFANILAMIDE

DRUG FEVER

P O HAGEMAN, MD
AND
FRANCIS G BLAKE, MD
NEW HAVEN, CONN

During a study of a series of cases treated with sulfanilamide at the New Haven Hospital,¹ a characteristic febrile reaction, which will be described in this paper, was encountered in a fair proportion of the cases. The term drug fever will be used to denote this complication of sulfanilamide therapy. Long and

Fig 1 (case 5)—Erysipelas and mastoiditis showing drug fever with a rash

Bliss² have mentioned the occurrence of fever following prolonged administration of sulfanilamide, as well as fever which appears promptly after large single doses of "Prontosil".³ Massell⁴ reported four cases of drug rash in a series of fourteen patients treated with sulfanilamide, but no data pertaining to time relationships and presence or absence of accompanying fever were included.

In a series of 134 cases of various infectious conditions treated with sulfanilamide, the reaction to be described was encountered in twenty-one cases (summarized in the accompanying table), an incidence of

15.6 per cent. Characteristics that distinguish this complication are fever occurring at a definite interval after the institution of sulfanilamide therapy with or without an accompanying morbilliform rash. In the majority of instances the reaction appeared between the seventh and tenth days of sulfanilamide therapy but in a few instances it came on as early as the fourth or as late as the thirteenth day. The onset of the febrile response

varied considerably as evidenced by variations in febrile response from normal to 106 F. As is shown in the table, the average duration of fever was from two to four days, with a definite prolongation in cases in which the drug was continued through the first few days of the reaction.

It will be noted that in four instances the reaction appeared from one to five days after the drug was dis-

* Discrepancies between per day and total columns depend on the time of day the dosage of sulfanilamide was begun, changed or discontinued. Sulfanilamide was given orally unless otherwise stated.
† Sulfanilamide was given subcutaneously.
‡ Sulfanilamide was given intrathecally.

was quite abrupt in many instances. Malaise, nausea, itching and tinnitus were the only subjective symptoms noted accompanying drug fever.

A rash accompanied the febrile reaction in nine cases. It was usually a maculopapular erythema, but definite hemorrhagic lesions as well as urticaria-like wheals were noted. The individual lesions varied in size from 0.3 to 4 cm. In the majority of instances the rash involved the face, trunk and extremities, usually being most marked over the buttocks, knees and back, where it tended to become confluent. Itching was present in the majority of instances. The severity of the reaction

continued. In two cases fever subsided in spite of continued administration of the drug. It is also of interest that in the majority of the remaining cases the dosage of sulfanilamide had already been reduced when the reaction made its appearance. Hepatitis with jaundice and stupor was present with the febrile response in one instance.

Laboratory data obtained during drug fever was variable. Leukocyte counts varied from 7,000 to 48,000, and the percentage of polymorphonuclear neutrophils varied from 63 to 95. Eosinophils were present in one half of the cases and ranged from 1 to 6 per cent.

Attempts to demonstrate the presence of precipitins for sulfanilamide in the blood serum during and following the reaction have failed, as have attempts to demonstrate sensitivity by patch and intradermal tests. Passive sensitization tests in human beings and guinea-pigs have also yielded negative results. Attempts to produce anaphylaxis and skin hypersensitivity in guinea-pigs have likewise failed.

REPORT OF CASES

To illustrate this specific reaction to sulfanilamide in detail, the following case histories are presented.

CASE 5 (fig 1)—Facial erysipelas, acute mastoiditis. A white man, aged 70, was admitted because of a spreading red lesion of the face of three days' duration. One month previously he had a cold, following which the left ear began to drain. Examination revealed a typical erysipelatosus lesion, discharging ear and tenderness over the left mastoid region. Culture of the ear showed beta-hemolytic streptococci. X-ray examination of the mastoid showed acute mastoiditis.

Treatment.—Sulfanilamide 12 Gm by mouth four times a day was given for two days, then 0.6 Gm by mouth four times a day for five days, a total of 207 Gm of sulfanilamide in seven days.

Result.—Erysipelas and mastoiditis subsided.

Reaction to Drug.—Cyanosis appeared during the first few days of treatment. On the seventh day the temperature rose

nation revealed dullness, increased voice and breath sounds and moist râles at the left base. X-ray examination of the chest after the injection of iodized poppy-seed oil showed bronchiectasis of the left lower lobe. Cultures of the sputum and bronchoscopic drainage revealed a predominance of beta-hemolytic streptococci. As the patient was to have a lobectomy, sulfanilamide was administered in an effort to rid the lung of beta-hemolytic streptococci.

Treatment.—Sulfanilamide 12 Gm by mouth every six hours was given for nine days, a total of 372 Gm in nine days.

Fig 3 (case 6)—Drug fever with a rash

Result.—Beta-hemolytic streptococci disappeared from bronchoscopic cultures on the eighth day of treatment.

Reaction to Drug.—Cyanosis developed during the first two days of drug administration. On the eighth day of treatment, fever followed by a generalized rash appeared, morbilliform to urticarial in type (figs 3 and 4). In addition, pruritus, anorexia and slight nausea were noted. Rash and symptoms subsided in three days.

CASE 13 (fig 5)—Acute streptococcal pansinusitis. A white girl, aged 15, was admitted because of swelling of the left eye and a nasal discharge. Three weeks before, the patient had had a "cold" and five days before developed frontal headache and profuse nasal discharge. Swelling of the left eye developed two days before admission. Examination revealed tenderness over the left frontal sinus. The left eye was swollen, especially at the inner canthus. There was a profuse purulent discharge from both nares. Culture of the nose showed predominance of beta-hemolytic streptococci. X-ray examination showed pansinusitis.

Treatment Prior to Reaction.—Nasal suction was applied daily. Sulfanilamide 12 Gm by mouth every six hours was given for three days, then 0.6 Gm by mouth every six hours for four days, a total of 25.2 Gm in seven days.

Result.—Sinusitis and swelling of the eye subsided completely.

Reaction to Drug.—Cyanosis promptly appeared after sulfanilamide was started. After a slight rise in temperature on the sixth day of treatment, the temperature suddenly rose to 105.5 F on the seventh day. No rash appeared. At first the fever was thought to represent a spread of infection, perhaps cavernous sinus thrombosis, brain abscess or meningitis, and sulfanilamide was increased to 1.2 Gm. every six hours for one day. Blood cultures were repeatedly negative. Culture of the nose at the time was negative for beta-hemolytic streptococci.

Fig 2 (case 5)—Morbilliform rash with definite hemorrhagic lesions

sharply and a diffuse morbilliform rash appeared. The rash became hemorrhagic on the eighth day, and pruritus was marked (fig 2). The only other systemic reaction noted was malaise. Rash and fever subsided in three days.

CASE 6—Chronic bronchiectasis. A white woman, aged 22, was admitted because of a cough of twelve years' duration. Subsequent to measles and whooping cough at 10 years of age, the patient began to raise foul, purulent sputum. Head colds accompanied by postnasal discharge had been frequent. Hemoptysis was noted on one occasion five years before. Exami-

High fever persisted and no localizing signs developed. A definite toxic psychosis accompanied the high fever. Sulfanilamide was discontinued on the third day of the reaction and the fever subsided gradually during the next two days. Recovery was uneventful.

CASE 17—*Streptococci meningitis and mastoiditis* A white girl, aged 13 years, entered the hospital because of an acute exacerbation of a chronic otitis media. Seven days before admission she had had a cold and five days later severe pain developed in the left ear. Chills, fever, nausea, vomiting, headache and stiff neck developed on the day of admission. Examination revealed stiff neck and bilateral Kernig signs. Marked nystagmus was present on looking to the right. The left ear drum was perforated and a discharge was noted in the canal. There was no mastoid tenderness. A culture of the discharge from the ear showed beta-hemolytic streptococci. The spinal fluid was cloudy and contained 850 cells (97 per cent polymorphonuclears). Smear and culture of the spinal fluid were negative for organisms. Mastoidectomy was done at once and culture of the mastoid cells contained beta-hemolytic streptococci. On the second postoperative day the temperature rose sharply. The spinal fluid contained beta-hemolytic streptococci on the third postoperative day.

Treatment Prior to Reaction—Sulfanilamide 0.9 Gm by mouth every six hours (starting on the second postoperative day) was given for four days, a total of 12.6 Gm in four days.

Result—Mastoiditis and meningitis subsided.

Reaction to Drug—Cyanosis appeared promptly after the drug was started. On the fourth day of treatment the fever began to rise, before the fever of the disease had subsided.

Fig. 4 (case 6)—Morbilliform rash with urticaria like wheals

Thinking that this represented a spread of the infection, we increased the dosage of sulfanilamide on the sixth day of treatment to 12 Gm every six hours. However, at this time meningeal signs had decreased and blood and spinal fluid cultures proved to be sterile. Nausea and malaise were the only subjective complaints during the reaction. Fever subsided after the drug was discontinued on the seventh day of treatment. Recovery thereafter was rapid and complete.

CASE 20—*Acute gonococcal salpingitis* A white woman, aged 18 years, was admitted complaining of pain in both lower

quadrants, dysuria and a vaginal discharge of two days' duration. The husband was known to have gonorrheal urethritis. Examination revealed tenderness in both lower quadrants, a profuse vaginal discharge, tenderness in both fornices, and a questionable mass in the right adnexal region. Smears from the urethra and cervix showed numerous gram-negative intracellular diplococci.

Treatment Prior to Reaction—For three days 12 Gm of sulfanilamide by mouth every six hours was given, then for three days, 0.9 Gm every six hours, a total of 23.1 Gm in six days.

Fig. 5 (case 13)—Pansinusitis with drug fever

Result—The discharge ceased, pelvic examination became negative and a smear from the cervix showed "occasional gram-negative cocci" at the time of the discharge of the patient from the hospital.

Reaction to Drug—Low grade fever and cyanosis were present during the second and sixth days of treatment. On the sixth day the temperature rose to 101.8 F and on the seventh day it reached 104.8 F. The drug was discontinued at this point and the temperature fell during the next two days. Malaise and tinnitus were quite marked during the febrile period. Recovery was uneventful.

CASE 21—*Erysipelas of leg ? Cholecystitis* A white woman, aged 53, was admitted with a story of chills, fever and a spreading red lesion on the left leg of five days' duration. Intermittent pain in the right upper quadrant had been present for years. The alcoholic intake had been excessive for the past four or five years. The patient was obese and there were varicosities and a typical erysipelatosus lesion of the leg. Some tenderness was noted in the right upper quadrant. Nonprotein nitrogen was 43 mg per hundred cubic centimeters.

Treatment—Sulfanilamide 1.5 Gm by mouth every six hours was given for three days, then 0.9 Gm every six hours for four days, a total of 33 Gm in seven days.

Result—The erysipelas cleared fairly promptly.

Reaction to Drug—Cyanosis was rather extreme, spectroscopic examination of the blood revealed evidence of methemoglobinemia, which by oxygen capacity studies was found to represent 16 per cent of the total hemoglobin. On the seventh day of treatment there was a sharp rise in temperature associated with jaundice and enlarged tender liver but no rash. The icteric index was found to be 40 and the nonprotein nitrogen had risen to 63. The bromsulphalein test revealed 40 per cent retention of the dye at thirty minutes. After the drug was discontinued the fever subsided over a period of three days. The jaundice gradually subsided. Eleven days after sulfanilamide had been discontinued the liver function had improved somewhat, there being a retention of 30 per cent of the bromsulphalein at thirty minutes. The icteric index was 30 and nonprotein nitrogen 29 at this time. The patient left the hospital against advice but seemed to be making an uneventful recovery at the time.

COMMENT

The reactions to sulfanilamide observed in this group of twenty-one cases seem to have definite characteristics that fall quite naturally into a single group. The similarity between drug fever and serum sickness is

rather striking. The time interval, the fever and the rash are characteristics common to the two. Generalized adenopathy and arthritis have not been observed in this series. The fact that the reaction occurs after the drug has been decreased in dosage or even discontinued suggests that it is not the immediate concentration of sulfanilamide in the body at the time of the reaction which is responsible for drug fever but rather that sulfanilamide itself or in a combined or changed form is antigenic. Thus far attempts to throw light on the mechanism of the reaction have failed.

As far as is known, drug fever has produced no permanent injury in this group of cases. Its occurrence, however, creates distinct diagnostic difficulties, especially in the absence of a rash and in cases in which the fever of the disease merges with drug fever.

TREATMENT OF LEFT VENTRICULAR FAILURE

FRED M. SMITH, M.D.
IOWA CITY

That failure of the left ventricle may occur before failure of the right ventricle, resulting in pulmonary congestion with perhaps little or no engorgement of the peripheral veins, explains the basic factors in the production of paroxysmal dyspnea commonly referred to as cardiac asthma. The conception of left ventricular failure is not new, for, as pointed out by White,¹ Weiss and Robb² and Harrison,³ it was clearly described by Hope in 1833. Unfortunately, however, it has been overlooked or disregarded for the most part by the recent generations of our profession until the past few years.

In the cardiac disability resulting from hypertension, arteriosclerosis of the coronary arteries, syphilitic aortitis and disease of the aortic valve, the dominant effect is on the left ventricle. This may finally terminate in insufficiency of the left ventricle before there is corresponding reduction in the functional capacity of the right ventricle, resulting in pulmonary congestion and thus a reduction in the vital capacity. Shortness of breath on exertion is often the first symptom and may be the only subjective manifestation for months. In some instances angina pectoris is the first expression of the cardiac disability and in others there is a history of severe and lasting anginal pain indicative of coronary thrombosis. Later, with further suppression of the function of the left ventricle without corresponding effect on the right ventricle and with the resulting increase in pulmonary congestion and the consequent reduction in the vital capacity, paroxysmal dyspnea may occur. Occasionally the occurrence of paroxysmal dyspnea is the first intimation of cardiac disease and under these circumstances is usually the immediate result of coronary thrombosis. Ordinarily, however, the conditions predisposing to paroxysmal dyspnea develop gradually. The attacks are precipitated by factors that increase the demands on the heart. They

may appear during the day following exertion or excitement, but later, in the course of the cardiac disability, they usually occur at night, awakening the subject from sleep.

Harrison and his co-workers,⁴ in the study of this subject, point out that various factors such as cough, abdominal distention, nightmares or dreams, and the desire to urinate, may precipitate nocturnal attacks and state that coughing, incident to the pulmonary congestion, and perhaps the associated bronchitis, is the most common and effective exciting agent. They have demonstrated that coughing produces a marked increase in the respiratory rate and conclude that this accelerates the return of the venous blood to the right side of the heart, which in turn aggravates the pulmonary congestion and thereby promotes the possibilities for continuation of the coughing. Thus a vicious cycle is perhaps instituted, which, unless interrupted, may progress to pulmonary edema and terminate in death. Of the various other factors that may contribute to the onset and progression of the paroxysmal dyspnea, apprehension deserves particular emphasis. After a few attacks, especially of the severe form, apprehension plays a significant rôle in precipitating subsequent attacks and no doubt is an important factor in producing the elevation of blood pressure. It is well to bear in mind that an abrupt increase in the already existing pulmonary congestion is primarily responsible for the paroxysmal dyspnea, regardless of the nature of the exciting agent.

Structural alterations of the heart are usually apparent from the increase in the size, particularly involving the left ventricle, the presence of gallop rhythm and possibly systolic apical murmur. Occasionally the gallop rhythm is the most conspicuous manifestation. There is often the history or presence of hypertension and it is frequently possible to demonstrate pulsus alternans. The intensity of the pulmonic second sound is commonly accentuated, more especially during attacks of paroxysmal dyspnea, because of the increased tension of the pulmonary circulation. The electrocardiogram often shows significant alteration of the character observed in disease of the coronary arteries. Pulmonary congestion is a prominent feature, generally evident from physical examination but more apparent from a roentgenogram. The reduction in the vital capacity reflects the extent of the pulmonary congestion and serves as a valuable guide in following the results from treatment.

During attacks of paroxysmal dyspnea the labored breathing, the apprehension and the pulmonary congestion, with perhaps edema, as evidenced by moist, sibilant and musical râles, dominate the picture. The cardiac rate is invariably accelerated and the blood pressure generally elevated above the usual level. Other changes, such as the gallop rhythm and the accentuation of the pulmonic second sound, are commonly prominent. In the more severe attacks the cyanosis, perhaps more often the ashen gray color, the profuse cold perspiration and pulmonary edema are conspicuous features.

In the consideration of the treatment it is important to bear in mind the following aspects of the condition:

1. An inadequate coronary circulation is commonly a prominent factor in the production of the cardiac disability.
2. Insufficiency of the left ventricle results in pulmonary congestion.

Read before the Section on Practice of Medicine at the Eighty Eighth Annual Session of the American Medical Association, Atlantic City, June 9, 1937.

3 With the progression of the cardiac disability and the maintenance of a disproportion between the efficiency of the left and right ventricles, a stage is finally reached which permits the occurrence of paroxysmal dyspnea.

4 The attacks are precipitated by factors that impose excess demands on the left ventricle. The onset in the more severe form often intensifies the exciting agent and initiates other factors which promote the pulmonary congestion, and thus a vicious cycle may be produced.

TREATMENT OF PAROXYSMAL DYSPNEA

The nocturnal attacks are usually aborted by the patient's assuming the upright position. The more severe form, however, is a major cardiac emergency and demands prompt and energetic treatment. Morphine sulfate 15 mg (one-fourth grain) is the most effective remedy and should be administered immediately and repeated if necessary. The effectiveness of this drug is due, no doubt, to the wide range of action involving both the function of the left ventricle and the pulmonary congestion. In the first place it curtails the demands on the left ventricle by eliminating anxiety and restlessness and the effect of these on the blood pressure. Moreover, morphine depresses the respiratory center, suppresses coughing and by these, and perhaps other means, reduces the tendency toward the progression of the pulmonary congestion.

The intravenous administration of theophylline with ethylenediamine 0.48 Gm in from 50 to 100 cc of 50 per cent dextrose solution is also very effective in preventing and abolishing attacks. This should be administered slowly. Improvement is usually apparent shortly after the injection is instituted, as evidenced by the influence on respiration and the relaxing effect on the patient. The results are attributed to the favorable action on the coronary circulation and the resulting increased efficiency of the left ventricle. Recently Greene, Paul and Feller⁵ of the University of Iowa have demonstrated that theophylline with ethylenediamine produces a marked reduction in the venous and intrathecal pressure. They have also verified the observation that it will frequently eliminate the bronchial obstruction of bronchial asthma and that it has similar action in paroxysmal dyspnea. The hypertonic dextrose solution is believed to enhance the effect of theophylline with ethylenediamine on both the heart and the pulmonary congestion.

In my practice, digitalis in the form of digifoline from 2 to 6 cc is often added to the theophylline with ethylenediamine and dextrose solution in order to produce the maximum effect on the left ventricle. The intramuscular or intravenous administration of ouabain 0.5 mg ($\frac{1}{12}$ grain) or amorphous strophanthin 1 mg ($\frac{1}{16}$ grain) is often recommended because of the prompt and powerful action. These drugs are dangerous if given in larger doses or if digitalis has been used.

Venesection is a valuable measure, particularly in the plethoric type of individual. The rapid withdrawal of 500 cc of blood from the veins of the arm at once reduces the venous return to the right side of the heart and thereby decreases the pulmonary congestion. It also diminishes the load on the left ventricle through the reduction in the blood pressure and the viscosity of the blood.

Similar effects with regard to the pulmonary congestion may be obtained by the procedure referred to as

venostasis, recommended by Danzer,⁶ Weiss and Robb⁷ and Harrison.⁸ The principle of the procedure is based on the reduction of the venous return to the right side of the heart through trapping the blood in the four extremities. This may be accomplished by the application of the cuff of a clinical sphygmomanometer as high up as possible on each of the extremities and the inflation of these to the pressure of from 60 to 80 mm of mercury. With the subsidence of the attack the pressure may be gradually released from one extremity at a time.

If the attack continues after one or more of these measures have been employed, the administration of oxygen should be instituted by nasal catheter if a tent or oxygen chamber is not available. In fact one should never rely on one remedy but combine as many as the circumstances justify.

Other drugs, such as glyceryl trinitrate, atropine and epinephrine, have been recommended in the treatment of paroxysmal dyspnea. With excessive elevation of blood pressure the use of glyceryl trinitrate is indicated because of its effect on arterial tension and action on the coronary circulation. It is doubtful however, that atropine has any significant value, and the administration of epinephrine is not advisable in disease of the coronary arteries.

The subsequent treatment consists of

1 Bed rest for from four to six weeks with complete relaxation and adequate sleep.

2 Simple diet with plenty of carbohydrates.

3 Regulation of the bowels by simple measures such as the administration of liquid petrolatum.

4 The administration of theophylline with ethylenediamine from 0.1 to 0.2 Gm ($\frac{1}{2}$ to 3 grains) from three to four times a day, digitalis (powdered leaf) 0.1 Gm ($\frac{1}{16}$ grains) three times a day for from five to six days and thereafter once a day, and the use of a mercurial diuretic if necessary to eliminate the pulmonary congestion.

5 Later the elimination or the control as far as possible of factors promoting the cardiac disability and finally the careful extension of the physical activities.

Time does not permit the discussion of each of these aspects of the treatment. Certain of them, however, deserve mention. The first concerns the prevention of the return of the nocturnal paroxysmal dyspnea. Adequate sleep is essential to the restoration of the cardiac function and is best obtained by the use of morphine. This medication is seldom required for more than a few nights. Thereafter simple sedatives, particularly when supplemented by theophylline with ethylenediamine, will produce the desired sleep and prevent the recurrence of paroxysmal dyspnea. The theophylline with ethylenediamine is more effective when given intravenously shortly before bedtime and, in my practice, is usually administered in 50 per cent dextrose solution. This method of use is reserved for the more advanced forms of cardiac disability and is ordinarily discontinued after a few days. The oral administration of theophylline with ethylenediamine is generally employed and continued indefinitely. The results from the prolonged use of the theobromine and theophylline preparation have been reported by Gilbert and Kerr⁹ and by me in collaboration with Rathe and Paul.⁸ Digitalis is necessary with auricular fibrillation.

and the intermittent use in small 0.1 Gm ($1\frac{1}{2}$ grain) doses daily is believed to be advisable with normal cardiac mechanism.

Finally the duration of rest and the subsequent extension of the physical activities deserve particular emphasis. The restoration of the heart to the maximum efficiency is obviously the primary objective. In view of the extent of the disability of the left ventricle this is not possible except by a long period of rest followed by the rehabilitation of the heart through the gradual and careful supervised extension of the physical activities. This aspect of the treatment is frequently slighted and no doubt is commonly responsible for the early return of symptoms. The patient should not be permitted to be up and about until long after the pulmonary congestion has disappeared. The subject, however, may have been free from nocturnal paroxysmal dyspnea for weeks and still have extensive pulmonary congestion. The determination of the vital capacity at weekly intervals provides a valuable means of following this feature of the recovery. If there is any question concerning the condition of the lungs, however, a roentgenogram should be taken. In the more advanced cases the use of salyrgan, perhaps preceded by the administration of ammonium chloride, may be necessary to eliminate the pulmonary congestion. The following case is cited because of the rather typical course and the difficulty encountered in controlling the pulmonary congestion.

G. F., aged 71, was first examined by me in December 1934. He had noticed shortness of breath for from three to four years and experienced the first attack of paroxysmal dyspnea in October 1933. In the spring of 1934, while returning from Florida, he was compelled to restrict his activities on two occasions because of asthmatic-like attacks. He had been awakened from sleep because of dyspnea for three or four nights prior to the examination. He weighed 200 pounds (91 Kg.), whereas the weight had formerly been 220 pounds (100 Kg.) for several years. The heart was quite large, the tones were poorly differentiated and there was an occasional premature beat. The systolic pressure was 190 and the diastolic 120 mm of mercury. Scattered rales were heard over the bases of the lungs. The electrocardiogram showed slurring of the QRS complexes, left axis deviation and negative T deflection in lead I. He was advised to take more rest and to avoid shortness of breath, and was prescribed theophylline with ethylenediamine 0.2 Gm (3 grains) three times a day and digitalis (powdered leaf) 0.1 Gm ($1\frac{1}{2}$ grains) once daily. The subsequent course was quite satisfactory until the appearance of the hot weather in July 1936, when the nocturnal dyspnea returned. In September, while away from home, he had very severe attacks. His wife mentioned in particular the ashen gray color and the profuse cold perspiration. With a period of rest he again improved, but following an upper respiratory infection in December 1936 he began to have frequent attacks of nocturnal dyspnea.

When admitted to the University Hospital in February 1937 he was very much worn out from the loss of sleep and weighed 180 pounds (82 Kg.). Slight exertion produced dyspnea, yet there was no significant distention of the jugular veins. The cardiac rate was moderately accelerated. There was a pronounced gallop rhythm, pulsus alternans and extensive congestion of the lungs. The systolic pressure was 170 and the diastolic 90 mm of mercury. The vital capacity was 1.5 liters. The treatment was as previously outlined. After five weeks of bed rest with sound sleep during the night and freedom from respiratory distress there was still extensive congestion of the lungs. This was eliminated by the use of salyrgan and ammonium chloride. Despite the continuation of the bed rest the pulmonary congestion returned in three or four weeks and was again eliminated by the mercurial diuretic administration in the form of suppositories. This patient is now up in a chair for a few hours each day, states that he feels fine, and presents a vastly improved general appearance, but it is obviously unwise to permit extension of his activities until the pulmonary congestion is controlled.

SUMMARY

Left ventricular failure characterized by the occurrence of paroxysmal dyspnea is a common form of cardiac disability. The treatment is concerned with the control of the paroxysmal dyspnea and the subsequent restoration of the cardiac function to the maximum efficiency. Ordinarily the attacks are readily abolished by the measures generally employed in the treatment of cardiac failure. The more severe form, however, is a major cardiac emergency and demands prompt and energetic treatment.

ABSTRACT OF DISCUSSION

DR. N. C. GILBERT, Chicago: Dr. Smith's paper concerns the treatment of an emergency frequently encountered and is of immediate and practical value. I would like to emphasize a point or two in which I am especially interested. The most important point which Dr. Smith brought out is the use of theophylline ethylenediamine in the treatment of the acute attack. I do not think that the fullest possible use is made of this and related preparations or that their value is fully appreciated. In many types of animal experiments, theobromine and theophylline have been shown to increase the coronary flow, and this has been substantiated by the clinical experiences of many observers over a long period. Dr. Smith has said that an inadequate coronary circulation is an important factor in the production of the cardiac disability, which is the basis of these attacks, and that the attacks themselves are precipitated by factors which impose an excess load on the heart. It would seem logical, then, to do as Dr. Smith has done and make use of a therapeutic agent to increase the coronary flow to the heart and to the left ventricle, and to combine this with the hypertonic dextrose solution to add further in overcoming the pulmonary edema which is part of the picture. I wonder how much of the cardiac disability following hypertension or resulting from coronary sclerosis, syphilis or old rheumatic carditis could be delayed or mitigated, if not prevented, by the early and continuous use of theobromine or theophylline preparations by mouth over a long period. I am sure that Dr. Smith will agree with me that they would be of definite value. Dr. Smith has shown the effect of theophylline in increasing the blood flow to the area of heart muscle deprived of its normal blood supply. Dr. Fenn and I believe, from our clinical experience that we have reason to assume a permanent improvement in the blood supply to the heart muscle induced by the long coronary dilatation and a consequent increase in anastomoses. Dr. Smith has spoken of the continuous use of theophylline by mouth in patients with left ventricular failure and paroxysmal dyspnea. This is of special value for the double purpose of improving coronary flow and of helping to eliminate any residual edema. It is of great importance that the lungs be edema free. We have reason to think that the presence of the edema predisposes to the acute attack. If edema does persist, we should make use of one of the acid base salts and a mercurial diuretic, as has been stated by the essayist. Digitalis may or may not be of value and it should be used in chosen cases with judgment and discrimination, and not in a routine manner. The use of glyceryl trimurate in cases associated with hypertension I consider of great value both for its effect on the coronary flow and for its effect on decreasing blood pressure. Morphine is, of course, almost a necessity. Between the attacks I consider the milder barbiturates of great value in quieting the apprehension which is undoubtedly a large factor in the attack. I also think venesection is overlooked and not used as much as it should be.

DR. R. D. BOCK, Corning, Ohio: I should like to ask a question. Morphine is emphasized, but I find patients who can't take morphine. How about codeine? That is what I have been using. It seems to work all right. Is there any objection to it?

DR. FRED M. SMITH, Iowa City: It is true that occasionally a patient is intolerant to morphine. Under such circumstances I usually use some other preparation. Codeine may serve the purpose.

LOBELINE SULFATE

ITS PHARMACOLOGY AND USE IN THE TREATMENT
OF THE TOBACCO HABIT

IRVING S. WRIGHT, M.D.

AND

DAVID LITTAUER, M.D.

NEW YORK

It is now generally accepted that the use of tobacco is definitely contraindicated in many conditions in which the circulation is impaired.¹ It often becomes necessary, therefore, for physicians to insist that patients suffering from such impairment stop the use of tobacco completely in any form and for the rest of their lives. We have advised termination of the tobacco habit in more than 100 cases during the past two years. If the physician is emphatic enough, pointing out clearly the dangers of continuing, the task can be accomplished in many instances without the strain anticipated by the patient. A certain percentage always remain, however, to whom sudden or even gradual deprivation of tobacco is a hardship. For this group substitutions such as gum chewing have been recommended from time to time but have been found generally unsatisfactory.

Recently Dorsey² presented an encouraging report on the use of lobeline sulfate as an aid to the breaking of the tobacco habit. The drug was recommended to be given orally in capsules, each containing 0.008 Gm (one-eighth grain), one capsule being taken every time a desire for a smoke was experienced. After a period of a few days, according to Dorsey's report, the desire for tobacco disappeared and the lobeline sulfate was gradually discontinued, leaving the patient with increased appetite and sense of well being and without the craving for "a smoke." A few unpleasant side actions such as nausea, anorexia and metallic taste were noted, but it was stated that these were only temporary and outweighed by the benefits.

Because a drug which would enable the confirmed smoker to give up this habit without hardship would be of obvious importance, and because lobeline resembles nicotine so closely in many of its pharmacologic properties, we undertook to determine whether or not it possessed any of those very actions which interdict nicotine for patients suffering from disease of the peripheral circulation and whether it could safely be widely used to help "cure" the tobacco habit.

PHARMACOLOGY

Lobeline³ is the principal alkaloid of *Lobelia inflata*, popularly known as Indian tobacco because it was believed to have been used by the aborigines in place of tobacco, although the Lloyds⁴ question seriously whether the Indians ever made use of the plant in the manner of a tobacco. Other alkaloids of the *Lobelia*

plant include lobelanine, lobelamine and lobelidine, with similar but weaker properties. The principal effects of the drug are considered as due to its action on the respiratory and vomiting functions and on the autonomic ganglions.

Edmunds⁵ believes emesis to be the main action of the drug in warm blooded animals, holding most symptoms secondary to the vomiting, which is medullary in origin. *Lobelia* was, in fact, the most important member of the class of "emetics" used by Sir Samuel Thomson and his followers in the early nineteenth century.⁴

In small doses lobeline has been held to be a powerful respiratory stimulant, lowering the threshold to carbon dioxide. In experimental animals large doses of it or its salt produce muscular twitchings, convulsions and even death from paralysis of the respiratory center.⁶ Because of its effect on the respiration the drug has been widely recommended in cases of narcotic poisoning, coal gas asphyxia and infectious diseases such as pneumonia,⁷ in respiratory failure during both general and spinal anesthesia⁸ and in asphyxia neonatorum.⁹ A considerable body of evidence has accumulated, however, discouraging the use of lobeline salts in respiratory failure. Curtis and Wright¹⁰ have found that the doses necessary to produce breathing have widespread effects on other systems, such as the heart, which may be dangerous. Others¹¹ have demonstrated that the drug is most effective when respiratory depression is slight or does not exist at all, while in profound depression the respiratory stimulus is often negligible. Camp,¹² after experimental studies on dogs, concluded that the drug was not a specific stimulant of the respiratory center and that all the other effects which it produces are due to the nicotine-like action on the autonomic ganglions. Following the work of Norris and Weiss,¹³ carbon dioxide has been widely used in place of lobeline to combat anesthesia asphyxia.

The direct and indirect effects on the general circulation have been carefully studied by several groups of observers.¹⁴ Lobeline causes sinus arrhythmia, partial bundle branch block and ventricular extrasystoles. After an initial pressor effect with rapid rise in the blood pressure there is a prolonged and dangerous fall below original levels, due probably to paralysis of the ganglions along the course of the vasomotor fibers and to direct poisonous action on the heart muscle. The drop in blood pressure is especially pronounced in deeply anesthetized animals.

3 Lobeline when not qualified by hydrochloride or sulfate is used in the broad sense like morphine.

4 Lloyd J U and Lloyd C G. *Drugs and Medicine of North America* 2: 65, 1886.

Lobeline was available in amorphous form only until Hermann Wieland¹⁵ in 1915 extracted a fairly pure crystalline compound, and Heinrich Wieland¹⁶ later determined the formula of the pure alkaloid. Two commercial preparations sold in this country as lobeline sulfate are lobeline sulfate-Merck, which, according to our information, is a mixture of the sulfates of alpha, beta and gamma lobeline, in unknown proportions, and lobeline sulfate-Mallinckrodt, which, according to our information, is a mixture of the sulfates of the total alkaloids of *Lobelia*. In other words, it may contain small amounts of alkaloids from *Lobelia* other than alpha, beta and gamma lobeline.

A crystalline hydrochloride of alpha lobeline has been sold under the trade name of Alpha-Lobelin. The Council on Pharmacy and Chemistry has refused to accept alpha-lobelin for inclusion in New and Non-official Remedies.¹⁷ "Lobeline sulfate" is not official in the U. S. Pharmacopeia or National Formulary and is not described in New and Nonofficial Remedies. It was believed that the crystalline hydrochloride, alpha-lobelin, possessed the respiratory stimulating action without the emetic action.¹⁸ However, others¹³ believe that the pharmacologic properties of the crystalline hydrochloride in animals and in men are essentially similar to those of the amorphous mixture of alkaloids or extracts of *Lobelia inflata* and that emesis does occur.

An evaluation of various lobeline preparations has been presented by Nisisita.¹⁹ He states that in rabbits a fresh solution of crystalline lobeline had the greatest toxicity and the strongest effect on the respiration. Lobelanine in relatively small doses produced convulsions. The emetic action was strongest with lobeline sulfate, it was felt that a decomposition product might accentuate or even produce this effect.

In recent years it has been found that injection of lobeline salts may be followed by a rise in the blood sugar.²⁰ The same effect may follow injection or even inhalation of nicotine²¹ and has been advanced as part of the explanation of loss of appetite and sense of satisfaction from smoking. This has been explained as secondary to its action on the adrenal medulla, which increases the rate of secretion of epinephrine,²² with resultant conversion of glycogen into dextrose.

METHODS OF INVESTIGATION

Lobeline was used in the form of sulfate, prepared in capsules of 0.008 Gm (one-eighth grain), as recommended by Dorsey, with an inert base of magnesium

oxide or starch. The preparations of Merck and Mallinckrodt were used in about an equal number of tests. The results obtained with these preparations were similar in different persons and at different times in the same person.

The subjects were divided into two groups, the first receiving the drug on varying schedules of dosage and noting symptoms therefrom, and the second receiving one or two doses during a test period while skin temperatures, blood sugars and capillaries of the skin were recorded or observed. Whenever possible, similar observations were made on the subjects of the second group following smoking of standard brand cigarettes. Control subjects were used in both groups.

Observations on Subjects Taking Lobeline Sulfate on Varying Schedules of Dosage—This group consisted of five subjects who did not smoke and twenty-eight who were confirmed smokers of cigarettes, pipes, cigars or combinations of the three. The subgroup of non-smokers contained three healthy normal adults and two sufferers from heart disease or peripheral vascular disease. The subgroup of smokers contained four normal persons and twenty-four victims of circulatory disease. In addition, four subjects representing healthy and diseased, smoker and nonsmoker, were used as controls. In the entire group there were twenty-eight men and five women.

Each subject was given a supply of capsules and put on a varying schedule of dosage. The smokers, whether normal persons or victims of cardiovascular disease, were instructed to take one capsule of the drug with a small amount of water whenever the urge to light a cigaret, cigar or pipe was experienced and to record symptoms if any developed. A limit of eighteen capsules in any one day was set for them, in accordance with Dorsey's observations that more than that number was never necessary. The nonsmokers were instructed to take one capsule of the lobeline sulfate three or four times daily and to record symptoms.

The four controls were given capsules containing only magnesium oxide.

The analysis of the observations in this experiment is considerably simplified because we noted no significant difference in the reactions of the so-called normal subjects and those suffering from circulatory disease, none between the two sexes and none between smokers and nonsmokers, except in the change in the desire for tobacco in members of the former group. In the group of those who smoked and who had been instructed to take a capsule of lobeline sulfate every time the urge for tobacco was experienced, a definite loss of this urge was experienced in almost every case after ingestion of even one capsule. The desire would return in a less acute form from half an hour to several hours thereafter and could again be easily satisfied, usually for several hours, by ingestion of a second capsule. Except for this observation on the loss of desire for tobacco, the results were uniform for the entire group, varying only in degree from subject to subject.

The symptoms produced by the oral use of this drug were predominantly gastro-intestinal. After one capsule they ranged from a few gaseous eructations, coming on within fifteen minutes after ingestion and persisting for from one to three hours, to severe "heartburn," boring epigastric pain, faintness, nausea and vomiting, appearing within from ten to twenty minutes after ingestion and lasting for from a few minutes to four hours. Metallic taste and salivation were common. One patient who took two capsules at once in error

vomited repeatedly during the following six hours. Other symptoms reported were lethargy, inability to concentrate, and a sensation of fullness in the head. Symptoms were less pronounced when the drug was taken on a full stomach. A characteristic of the reports was that the symptoms referable to the gastro-intestinal system would undergo recrudescence anywhere from fifteen to sixty minutes after they had subsided.

Despite the instructions to those who smoked not to hesitate to take as many capsules, up to eighteen daily,

The following three histories are quoted as typical of the series. A research engineer who took one capsule daily for ten days reported that he lost all desire for "a smoke" but that after the first day he did not eat well, could not concentrate as well as he could with nicotine and felt generally miserable. The junior author (D. L.) of this report, a confirmed smoker of pipes and cigarettes, took four capsules on one day and three on the next. There was mild epigastric pain following the first dose, slight discomfort following the

as their desire for tobacco indicated, and to those who did not smoke to take three or four capsules daily, not a single subject would willingly take more than three capsules a day for longer than three days. A number of patients did not wish to take a second capsule following their experience with the first. It is true that among those who smoked the desire for tobacco was lost on this dosage, but it was equally true that in the entire group, whether smokers or not, whether normal or suffering from cardiovascular disease, whether men or women, the appetite for food was also markedly diminished, and other extremely unpleasant side actions were experienced so long as the effects of the drug were pronounced enough to inhibit the desire for smoking.

second and none thereafter. A few minutes after each dose, definite salivation and a metallic taste in the mouth were observed. On the evening of the first day there was moderate desire for tobacco, easily requited by ingestion of the fourth capsule for that day. On the second day no such desire was in evidence. He ate little lunch on the second day and less dinner. He was unduly lethargic on the evening of the second day. Three days after cessation of the experiment he took one capsule as part of the investigation to be described and ten minutes after ingestion experienced severe boring epigastric pain which persisted for about twenty minutes, subsided gradually, recurred in milder form ten minutes later and lasted for almost an hour there-

after A patient who took a daily dose of 0.008 Gm (one-eighth grain) of lobeline sulfate three times daily for three days reported "an unpleasant, unsettled feeling in the stomach, flat taste in the mouth, and considerable belching."

The control group experienced no symptoms whatever.

Observations on the Temperature of the Skin, the Capillaries and the Level of the Blood Sugar in Patients Given Lobeline Sulfate and Smoking Tobacco Under Test Conditions—In this group were seven subjects who did not smoke and five who smoked cigarettes alone or cigars or pipes in addition, in varying amounts. Of the nonsmokers, two were healthy normal persons and five suffered from peripheral vascular disease. Of the smokers, one was a healthy normal person and four were victims of heart disease or peripheral vascular disease. Two additional subjects were used as controls. In the entire group were ten men and two women. Their ages ranged from 29 to 67.

Each subject was given one capsule of 0.008 Gm of lobeline sulfate orally, and observations on skin temperatures, capillaries and blood sugars were made, fol-

Chart 1—Skin temperature study March 29 1937. J. S., a man aged 54, Jewish, had generalized arteriosclerosis, recent coronary occlusion and peripheral sclerosis with intermittent claudication. The hands were exposed at room temperature for one-half hour before readings were made. Blood for sugar determinations was taken from the right antecubital vein. Capillary studies were made on the fingers of the right hand. The patient had a breakfast of prunes and coffee three hours before the first blood specimen was taken. He smoked one cigarette two hours before readings were begun.

lowing the methods to be described. The two controls were given capsules containing magnesium oxide. The results are summarized in table 1.

The observations were repeated, in the case of the five smokers, with inhalation of the smoke of one standard brand cigarette in place of lobeline sulfate (table 2). As both hands of the subject were occupied during the test, the cigarette was held by an observer while the subject took deep breaths and inhaled at a moderate rate. As the effects of tobacco smoking on normal control individuals have already been established by ourselves and by others,² we did not include them in this phase of the experiment.

Recording of Skin Temperatures—The subjects were seated in a draftless room the temperature of which ranged between 22 and 24 C (71.6 and 75.2 F). They were adequately clothed. The left hand was placed on a table covered with several thicknesses of paper toweling. Readings were taken by a Leeds and Northrup potentiometer with iron, copper, platinum, chromel and alumel thermocouple junction from the first, third

and fifth fingers just proximal to the nail fold, from the dorsum of the hand, and from the nuchal forehead. The subjects sat quietly in the room for at least half an hour or as long as necessary to establish a stabilized temperature level. At first the skin temperatures were recorded every ten minutes, after stabilization had occurred and during the test they were recorded every five minutes.

Observation of the Skin Capillaries—The nail folds of the fingers of the right hand were cleaned with benzene and alcohol. The nail fold of one finger was observed through the capillary microscope for changes in number, in size and shape of the stream and in rate of flow. Capillaries were observed several times before and at ten minute intervals after the test was begun.

Determination of the Blood Sugar Levels—The blood was drawn from the antecubital vein of the right arm. Whenever possible a tourniquet was not used, light pressure being applied to the upper arm instead to obviate changes in the capillary picture in the fingers of this extremity, from this procedure. Analysis of blood was by the technique of Folin and Wu.

Specimens were taken a few minutes before lobeline sulfate was ingested or a cigarette was smoked and again twenty, forty and sixty minutes after ingestion or commencement of inhalation. The observations were so timed that the initial blood specimen was drawn at least three hours after a light breakfast, except in case 7 (I. S., a diabetic patient, on whom observations were made on a fasting stomach).

RESULTS IN SUBJECTS RECEIVING LOBELINE SULFATE ORALLY

As in the first part of the study, following the ingestion of lobeline (in the form of its sulfate) the symptoms were predominantly gastro-intestinal and ranged from a few gaseous eructations, which appeared a few minutes after ingestion, to severe boring epigastric pain, which necessitated termination of the portion of the experiment concerned with skin temperature readings in two cases. Other reactions were dizziness and drowsiness. No change in respiration was observed except in the presence of severe pain or nausea.

Of the ten studies in which skin temperature readings were possible, in two the temperature of the nail folds fell at least 2 degrees C (3.6 degrees F), in two more it fell at least 4 degrees C (7.2 degrees F), in six there was no appreciable change. Depression of temperatures was coincident with the onset of gastro-intestinal symptoms in each case in which it occurred, but the severity of the symptoms had no relation to the extent of the drop.

In two of the ten cases in which blood sugar levels were determined there was a definite rise in the blood sugar of 55 and 64 mg per hundred cubic centimeters respectively within one-half hour, and then a fall to normal by the end of an hour. In two cases the blood sugar fell 18 and 22 mg. Five cases showed no change, in a sixth case there was a rise of 5 mg per hundred cubic centimeters, not considered significant. The two patients exhibiting the hyperglycemia also experienced severe gastro-intestinal symptoms, one also showed a drop of skin temperature, and in the other, after an initial slight fall, readings had to be discontinued because the patient jumped up and began to massage his abdomen vigorously with the hand from which temperatures were being taken.

In no subject were significant differences in the number, size and shape of stream or rate of flow of

the capillaries observed before and after ingestion of the drug. In none were there changes in respiration, with the exceptions noted.

RESULTS IN SUBJECTS INHALING SMOKE OF STANDARD CIGARETS

The five smokers in the group receiving lobeline sulfate were the nucleus of this observation.

Symptoms from deep inhalation included nausea, palpitation, slight headache, dizziness, tingling in the toes and, in one case, clammy perspiration.

In three of the five cases the temperature of the nail folds of the fingers fell 2 degrees C or more, commencing during the period of smoking and remaining at the lower level for at least one hour thereafter. In one case no change was observed. The fifth subject, who broke into a sweat during deep inhalation (he was accustomed to superficial puffs only) exhibited a rise in finger temperature of 3 degrees C (5.4 degrees F). The temperature of the dorsum of the hand did not change appreciably in any subject, and, except in the subject who perspired, the forehead temperatures did not change at all.

Chart 2—Skin temperature study April 1 1937 on same patient as in chart 1. The hands were exposed at room temperature one hour before test readings were made. The blood for the sugar determination was again taken from the right antecubital vein and the capillary studies were made on the fingers of the right hand. The patient had breakfast three hours before the initial blood sugar reading was made. He smoked his last cigaret one hour and a half before the readings were begun.

Blood sugars in two of the five cases showed definite elevations of 15 and 76 mg per hundred cubic centimeters within one-half hour, and a fall to original levels by the end of one hour, in two cases there were rises of 5 and 8 mg, considered too slight to be significant, in the fifth case the level of blood sugar was unchanged during the period of observation. The rise of 8 mg occurred in the subject who reacted to smoking with dizziness, perspiration and a rise in finger temperature.

Two subjects whose skin temperatures fell likewise exhibited definite slowing of the rate of flow in the capillary stream in the nail folds. No changes in the number of the capillary loops or in the size and shape of the stream were observed. The accompanying two charts show almost identical curves of skin temperatures in the fingers and blood sugar levels in one subject who participated in both parts of the experiment. Such definite results were by no means the rule, we merely point out the parallelism that can occur following inhalation of cigaret smoke and ingestion of lobeline. The patient was a stable individual desirous of giving up smoking, thoroughly cooperative and interested in the experiment, and we believe that emotional factors were at a minimum.

COMMENT

Recent studies have established the fact that the use of tobacco is definitely contraindicated in the presence of certain pathologic processes, for example, diseases producing impairment of the peripheral circulation, and gastric and duodenal ulcers. The problem of forcing complete abstinence from tobacco on certain patients has become a major one in medical practice. Any means of overcoming a long standing tobacco habit with a minimum of inconvenience to the patient would be an important addition to the therapeutic armamentarium. And yet the usefulness of any "cure" is curtailed if it is too disagreeable.

We therefore investigated the possibilities of lobeline sulfate as a substitution medication. Our experiences lead us to conclude that the effects of ingestion of the drug are too unpleasant to warrant its use for this purpose in the doses recommended. Not only does it produce gastro-intestinal symptoms that run the gamut, from a few eructations to severe nausea, epigastric distress, and even vomiting, but it also causes loss of appetite, states best described by patients as an "unsettled feeling," and in some cases diminished ability to carry on the daily routine. Patients will not willingly take a drug which causes them to suffer epigastric distress or to vomit at unpredicted times. They prefer to stop smoking through effort of will. The crystalline, pure salts appear to be as guilty as the amorphous drug with respect to action on the gastro-intestinal system.

The results of the second part of the experiment, although not conclusive in such a small series, indicate nevertheless a trend toward nicotine-like action with regard to the circulation of blood through the small vessels of the extremities. After ingestion of the drug some cases showed, like nicotine, a definite drop in skin temperatures, none showed an upward tendency. This effect of a small dose of the drug by mouth is in accord with the experimental work of Camp¹² on animals. He states:

If the superior cervical ganglion of a rabbit is painted with alpha-lobelin, a definite constriction of the ear vessels is seen. Following this there is a dilatation. Stimulation of the pre-ganglionic fibers and the ganglion itself produces no effect, while stimulation of the postganglionic fiber produces a constriction. This is absolute evidence that the ganglion is no longer able to transmit impulses. I conclude, then, that as with nicotine the change in the caliber of the blood vessels and hence the change in blood pressure is for the most part due to the stimulation of the ganglion cells to the blood vessels, the rise from activation of the constrictors, and the fall from activation of the dilators, and vagus action on the heart.

Any drug that causes a vasoconstriction, even though it is temporary and even though the drug is used for only a limited period, is contraindicated in diseases of the circulation due to spasm or occlusion of blood vessels.

The effect of lobeline sulfate on the blood sugar level was not constant in this series in which the drug was given by mouth, although marked rises were noted in two cases. Following inhalation of tobacco smoke there was either a rise or no change in the blood sugar level.

No demonstrable change in the rate of respiration was noted in those who took varying amounts for a period of days or in those who took single doses of 0.008 Gm under close observation, except in those subjects who experienced nausea or pronounced epigastric pain. Blood pressures of several members of the former group also showed no change.

In this clinical study we confined our observations to the effects of the oral administration of the drug to

human beings, because of the purpose for which the drug was recommended. In such circumstances, actions are admittedly variable and not sharply defined. Careful experimental work on animals, in which parenteral routes of administration were used, have been noted throughout this paper. King, Hosmer and Dresbach¹¹ cite the case of a healthy human subject given 0.21 mg per kilogram of alpha-lobelin²³ intravenously. Within thirty seconds he had inspired deeply several times, groaned, become pale, rolled his eyes and experienced knifelike precordial pain and dizziness. There was no nausea or vomiting. Hyperglycemia occurred. Norris and Weiss, giving twenty-one men doses of from 10 to 20 mg of alpha-lobeline subcutaneously or intramuscularly, found no appreciable stimulation of respiration but many of the unpleasant gastro-intestinal side actions which we noted following oral administration.

The question of dosage of lobeline sulfate is important. It is possible that a smaller amount of the drug might achieve the desired effect without the unpleasant side actions. We have tried a few subjects with 0.004 Gm (one-sixteenth grain) capsules, to be taken when the urge for a smoke manifested itself. Thus far we have found one in four who states that his cigaret smoking has fallen off almost completely, his appetite has improved and generally he feels better. The other three do not report similar success, one suffered from mild nausea which did prevent smoking, one had a vague unsettled feeling with no effect on his desire to smoke, and the third noted no results of any sort whatever.

The drug by its undesirable effects appears self-limiting as to dosage. In view of its established toxicity, however, a note of warning should be sounded against the use of the large doses mentioned by Dorsey,² especially in those patients with cardiac disease or peptic ulcers, who together constitute a large portion of the patients for whom heavy smoking is inadvisable.

Finally, the problem of the permanent status of the patient with respect to his former habit arises when he has gone so far along the road to complete abstinence from tobacco that he no longer requires substitution medication. Typical is the experience of the patient suffering from thrombo-angitis obliterans, whom we have followed for three years. From a peak of heavy smoking he has brought himself down to a level of two or three cigarets daily, and there he has remained. He eagerly agreed to become one of the subjects for investigation. He took one capsule a day for three days, during which period he had no desire to smoke, but at the same time his appetite fell off in such alarming proportions that he discontinued the drug after the third day. On the fourth day there was still no urge to smoke, but on the fifth day it became manifest, and he succumbed and lit a cigaret. If he had continued to take the lobeline sulfate the nicotine-like effect would still have been present in his system and the object of abstinence from tobacco defeated. In the last analysis no substitution drug or product which will tide a patient over the period of transition from smoker to nonsmoker will prevent him from resuming the pleasant habit when it is stopped. Only the combination of clear and emphatic explanation on the part of the physician, and determined cooperation on the part of the patient, will accomplish this desired end.

²³ King, Hosmer and Dresbach¹¹ and Norris and Weiss¹² worked with the proprietary preparation alpha lobelin. It was partly on the basis of the work of Norris and Weiss¹² that alpha lobelin was declared not acceptable for New and Nonofficial Remedies (J. A. M. A. 100 1933 [June 17] 1933).

CONCLUSIONS

1 Lobeline sulfate in doses of 0.008 Gm (one-eighth grain) orally is not suitable for general use as a "cure" for the tobacco habit. The symptoms are predominantly gastro-intestinal, variable from patient to patient, and in general too drastic in most individuals.

2 Lobeline sulfate produces a nicotine-like effect on the peripheral circulation. In certain individuals a vasoconstriction with a drop in surface temperature occurs. This is not as constant, when the mentioned dosage and route of administration are used, as the effect obtained by smoking a cigaret.

3 Lobeline (administered in the form of lobeline sulfate), like nicotine, produces an elevation in blood sugar in certain individuals.

4 Further study with smaller doses may increase its usefulness for the purpose, but its widespread use should not be encouraged until such studies have been completed.

Clinical Notes, Suggestions and New Instruments

MENINGO-ENCEPHALITIS AND RUBELLA

CHARLES F. READ, M.D., ELGIN, ILL.

The occasional occurrence of meningo-encephalitis in connection with many of the acute exanthems is well established. Few cases, however, have been reported in connection with rubella. German measles has the reputation of being an innocuous disease, in fact, so harmless that the public often makes its own diagnosis and does not even consult a physician. In view of this situation, it seems proper to call attention again to the fact that encephalitis occurs in connection with this disease and to report an additional case.

In 1929 Brock related a case in which severe occipital headaches developed in a woman, aged 23, three days after the appearance of a rash, with rigidity of the neck, divergent strabismus and Babinski reflex on the right side. This case is included in the tabulation of Merritt and Koskoff.¹ These authors, however, do not cite the case, with autopsy, reported by Briggs.² A white boy, aged 10 years, after apparent recovery on the third day, was permitted to play in the snow. Immediately following this exposure paraphasia, lateral nystagmus, slight papillary edema, paresis of the right arm, and Babinski, Gordon and Oppenheim reflexes of the right leg developed, and then a convulsion, after which the left leg also showed pathologic reflexes. "Alternating spastic and flaccid paralysis" of both lower extremities then occurred and the temperature rose to 107 F (pneumonia). The spinal fluid was clear, the cells numbered 51 and were practically all lymphocytes and sugar was 65 mg. Death occurred within twelve hours of the onset of symptoms.

The postmortem examination in this case is perhaps the only one on record with any report of the pathologic changes of the brain, and in this respect it is somewhat incomplete. The gross manifestations were bronchopneumonia and petechial hemorrhages of the white substance of the brain. Microscopically there was "definite perivascular infiltration of lymphocytes and polymorphonuclear leukocytes at many points. In certain areas the small vessels were also surrounded by collections of red blood cells."

The same author mentions personal knowledge of at least three other encephalitic sequelae in the same epidemic, aside from the two cases reported at some length and here recorded.

Merritt and Koskoff's article deals with four cases seen in a Massachusetts epidemic early in 1935, describes these in detail and presents tabulations of the neurologic signs and symptoms.

Read before the Chicago Neurological Society, Feb. 18, 1937.

¹ Merritt H. H. and Koskoff J. D. Am. J. M. Sc. 191 679 696 (May) 1936.

² Briggs J. F. J. Pediat. 7 609 (Nov.) 1935.

in seven other cases gathered from the literature, omitting, however, the aforementioned case of Briggs as well as a few others.

The patients (eighteen as tabulated by me, including my own) ranged in age from 3 to 33 years, with a slight preponderance of males (ten). The onset occurred from two to seven days after the appearance of the rash. Headache was rather common (eight cases), convulsions were frequent (nine), rigidity of the neck was less frequent (five). Mental confusion, or stupor, was often present (thirteen). Nystagmus, diplopia, strabismus or conjugate deviation occurred in seven cases. Paresis or paralysis was mentioned specifically in only four cases. Babinski's toe sign was noted in ten and cerebellar signs in but two. The febrile reaction apparently was not considered important enough to report in the majority of cases but ranged up to 104 F.

Examination of the spinal fluid showed but one patient with a measured increase of pressure (400 mm of water). The cell count varied from 5 to 400. The protein was increased in six of the seven cases examined. The sugar of the spinal fluid when determined was never beyond normal range. In five cases (Merritt and Koskoff's¹ and Goudron's²) the colloidal gold reaction was moderately increased in the middle range in four. One was entirely negative.

REPORT OF CASE

E. K., a white man⁴ aged 26 was seen Feb 18, 1936, during an epidemic of rubella which involved many adults. At the time of examination the diagnosis of encephalitis had already been made, the problem merely being that of prognosis and treatment. The patient had complained on February 8 of aching, with no symptoms of ordinary measles. He stated that on the 12th a moderate rosy colored eruption developed on his chest, which lasted only about a day. The next day he went to work as usual, but two and a half days later he came home (driving 3 miles) with thickened speech, loss of equilibrium and dizziness. He rapidly became worse. A few hours later projectile vomiting, without much nausea, developed and he was then seen for the first time by his family physician and sent to a hospital.

When I examined him on the 18th he was evidently very ill, with some twitching of the fingers and thickened rambling speech, though he answered a few questions slowly and to the point. Although he complained of diplopia, there was no noticeable strabismus but a lateral nystagmus. The pupils reacted to light and in accommodation, and the fundi were normal. There was rigidity of the neck, but the Kernig and abnormal reflexes were absent. The knee jerks were exaggerated. Paralysis did not exist as far as could be ascertained in his semistuporous state. The condition of the patient was not conducive to adequate testing for cerebellar involvement.

Spinal puncture on the third day of the acute illness returned clear fluid; pressure was apparently increased but not measured; cells numbered 4, globulin was negative, sugar was 88 mg and the Wassermann reaction was negative.

There were 4100000 red cells, 8650 white cells, with polymorphonuclear leukocytes 74 per cent, lymphocytes 20 per cent and large lymphocytes 6 per cent. After the withdrawal of 10 cc of spinal fluid the patient appeared to improve and another puncture was done on the 19th for further removal of fluid. Treatment consisted of sedatives with dextrose by proctoclysis and intravenously. Nursing notes of February 16 showed almost continuous twitching of the fingers and of the arms and shoulders at times complaints of dizziness (although confined to bed) and vomiting. Vomiting continued on the 17th with hiccups. The patient was continent, voided and moved the bowels. Hiccups were again noted on the 18th as well as vomiting but the patient was reported to be better. Headache persisted for several days (possibly post puncture?) but he rapidly improved and on the 21st sat up, with the help of a backrest, to eat.

On the eighth day after the onset, headache was still present and he felt 'tired'. On the 25th he was still dizzy and had headache but was sent home on the 26th, the tenth day after the onset of encephalitic symptoms. He remained a few days in bed, rapidly convalesced and was at work within a month of the onset, though he said that he fatigued easily for a year afterward.

The temperature never rose above 99.2 F. the pulse was slow (between 40 and 60) until convalescence was well established, respiration was not affected. Paralysis did not develop. Vomiting, dizziness and loss of equilibrium together with lateral nystagmus and diplopia, were outstanding features. Headache appeared only after the spinal puncture.

The patient has remained well up to the present time aside from an operation for acute appendicitis. Concerning his illness he later said: 'My mind was clear but worked slowly. I knew what was going on about me except at one time when I thought I was in some great laboratory. I had to concentrate on any movement and then after I had worked awfully hard to move the hand and arm an inch or two it would fly up high past where I wanted it to go (cerebellar ataxia?). My tongue felt 2 inches thick but I could get the right words if I had time enough.'

CONCLUSIONS

Another case of encephalitis associated with rubella is added to the limited literature on this subject. Six cases are added to Merritt and Koskoff's list of May 1936 bringing the total in the literature up to eighteen.⁵ There were two deaths, a percentage of 11.1. One of these was probably attributable to pneumonia. Although the percentage of patients with rubella in whom encephalitis develops is not large, the possibility of this complication should be kept in mind especially in view of the frequency of German measles and the apparently innocuous character of the disease.

Elgin State Hospital

IMPROVED METHOD OF USE OF LATEX

JOSEPH K. NARAT, M.D., CHICAGO
Attending Surgeon, St. Elizabeth Hospital

In the last few years latex has been recommended repeatedly as a substitute for collodion in dermatology. Straus¹ recommended its use in surgical conditions particularly for the protection of skin edges around an enterostomy. The disadvantage of the natural rubber latex is the occasional occurrence of fermentation. It occurred to me that a synthetic latex might overcome this difficulty.

Du Prene' latex² is made by emulsifying chloroprene in water and allowing it to polymerize under carefully controlled conditions. The resulting product resembles vulcanized natural rubber latex but contains neither bacteria, sugars nor proteins, therefore there is no danger of instability due to fermentation.

Difficulties were encountered in obtaining a uniform film of "Du Prene" latex on the skin. Therefore an attempt was made to mix normal rubber latex with an alkaline 'Du Prene' latex. It was found that unless special precautions are taken coagulation immediately occurs. Stabilized alkaline 'Du Prene' and natural rubber latices may be made in accordance with the accompanying formulas.

Stabilized 'Du Prene' Latex

Du Prene latex (45% Du Prene)	Cc
29% aqueous ammonia	100
15% Aquarex D solution	2

The Aquarex D solution should be mixed with the ammonia before it is added to the latex.

Stabilized Normal Rubber Latex

Normal latex (about 37% solids)	Cc
15% Aquarex D solution	100
	12

If this stabilized rubber latex is poured slowly into the stabilized "Du Prene" latex with careful stirring no coagulation or flocculation will occur. A mixture of 25 cc of the stabilized rubber latex with 100 cc of stabilized alkaline 'Du Prene' latex is recommended. Films deposited from mixtures

⁵ Cases not included in Merritt and Koskoff's review include Epstein and Loup, *Rev. med. de la Suisse Rom.* 50: 161 (March 10) 1930.

¹ Straus, F. H., *Prevention of Skin Digestion in High Intestinal Fistulas*, J. A. M. A. 105: 1345 (Oct. 26) 1935.

² The product was supplied by E. I. DuPont de Nemours & Co. Inc. Made by dissolving 15 Gm. of Aquarex D in 85 cc of water. The product is manufactured by E. I. DuPont de Nemours & Co. Inc.

of the two types of latex are softer and more flexible at room temperature than are those formed by the natural latex alone.

This improved latex is a cheap and efficient substitute for the collodion, over which it has the advantage of being very flexible and more adherent to the skin. No fermentation occurs in the suggested mixture. The product is especially recommended for the protection of the skin in the vicinity of artificial orifices, such as gastrostomy, enterostomy, cystostomy and ureteral fistula.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

THE PRESENT STATUS OF VINETHENE

The Council published a preliminary report on Vinyl Ether—Merck in 1934,¹ deferring consideration of this anesthetic agent until additional evidence had accumulated and until the firm marketed the product. The Council has recognized the firm's right to the name Vinethene. It was, therefore, necessary to consider the evidence which has accumulated since 1934 (when the preliminary report was published) in order to determine the acceptability of the product itself, its indications and contraindications as well as its limitations and safety.

EXPERIMENTAL OBSERVATIONS

Pharmacology—Bourne,² who studied the drug experimentally and clinically, noted that it is not useful in experimental animals. Nevertheless it is extremely important that due consideration be given to the experimental observations that have been reported. The variations in its effects on human beings and animals may be due to an actual difference in susceptibility, but the present evidence does not warrant granting this surmise.

Vinethene, which is essentially divinyl ether, $\text{CH}=\text{CH}-\text{O}-\text{CH}=\text{CH}_2$, differs from ether, U.S.P. (diethyl ether, $\text{CH}_3-\text{CH}_2-\text{O}-\text{CH}_2-\text{CH}_3$) in that it is a more toxic agent although there is a corresponding decrease in the concentration necessary for anesthesia, which may be an advantage if it is properly employed. Goldschmidt³ noted that the absolute difference between the anesthetic and lethal concentrations in the blood was about the same in dogs for the two ethers, but he also noted a ratio of 1 to 7 for concentration necessary for anesthesia in human beings, whereas in animals the ratio had been calculated to be about 1 to 4 (vinethene to ether). He considered the lethal concentration to be about one-half that for ether in animals. According to these figures, vinethene would be twice as safe as ether for animals, but this has not been borne out by subsequent evidence.

Recently Molitor⁴ of Merck & Co. has made a rather extensive study of the toxic effects of Vinethene. The toxicity was studied according to the method of Fuehner.⁵ Molitor also checked the studies of von Brandis.⁶ He administered Vinethene to 5,000 white mice and gave ether to 300 control animals. He considered the toxicity of the two ethers similar and confirmed

the observations of von Brandis in noting that 360 of 445 mice which recovered from the anesthesia died later—mostly during the succeeding fifteen hours. Neither Molitor nor von Brandis was able to determine the cause of death in these cases, but Molitor believed that anoxemia and respiratory complications could be excluded because a control series using premedication with atropine and carbon dioxide absorption technic gave essentially the same results. He expressed the opinion that the late deaths might be due to a racial hypersensitivity, since rats exposed to the same procedure did not succumb in this manner. He concluded that the lethal dose (dose producing 50 per cent mortality) of ethyl ether is 180 millimols per liter of air, of chloroform 0.32 millimol per liter of air, and of Vinethene 2.11 millimols per liter of air.

Effects on the Liver—Goldschmidt and his co-workers³ reported liver necrosis in dogs after several hours of Vinethene anesthesia and later studied the relation of anesthesia to liver damage. They reviewed the work of Leake, Knoefel and Guedel⁸ and studied liver damage following chloroform, Vinethene and ether administered by means of a Gwathmey three chamber volatilizer with the addition of a reservoir between the volatilizing chambers and the mask in dogs on a normal and high carbohydrate diet. They used sodium amytal anesthesia to indicate that the anesthetic state itself was not responsible for these changes but that they were due to the inhalation of volatile anesthetic agents. They found that necrotizing effects of chloroform and Vinethene on the liver cells of the dog are largely prevented by administering the anesthetic with oxygen. High carbohydrate diet was as effective as oxygen in protecting the dogs against chloroform and more effective in protecting them against Vinethene.

Other Experimental Observations—Bourne and Raginsky^{2c} noted that dogs which developed cyanosis during anesthesia developed liver necrosis but that otherwise there was no effect even on livers previously damaged by chloroform. Essex⁹ reported uniformly rapid induction in rabbits and marked variation of induction in dogs. Goldschmidt³ noted running movements in dogs in which it was difficult to maintain anesthesia, and Waters¹⁰ reported these running movements so marked that he thought he was dealing with a different drug and discontinued his experiments. Later he repeated his experiments and noted the same phenomena even when the anesthetic was pushed. Molitor⁴ found that the rapidity of induction in mice was dependent on the temperature although rapidity of recovery was not.

Irritation and Possible Contaminants—Although Vinethene is said to be less irritating than ether, Goldschmidt³ noted a considerable amount of mucus in dogs (and human beings). It developed after Vinethene had been administered for a short time and even in cases in which atropine sulfate had been given. Leake¹¹ thought that the mucus was due to minute traces of impurities such as formaldehyde or formic acid, which are extremely irritating in very small amounts not detectable chemically. On the other hand, Molitor⁴ found decomposed Vinethene no more toxic than the pure agent in mice.

Since the publication of these reports, the A. M. A. Chemical Laboratory has found the product as marketed (Vinyl ether with 0.01 per cent of phenyl α -naphthylamine and 3.5 per cent absolute alcohol) satisfactory from a chemical standpoint.

Ravdin and his associates¹² point out that they do not know the lethal concentration of the anesthetic in man but that it probably does not exceed that of the dog, which is 68 mg per hundred cubic centimeters of blood.

CLINICAL EXPERIENCES

Period of Anesthesia and Liver Damage—Consideration has already been given to the experimental evidence of liver damage resulting from this anesthetic and the clinical experiences follow

Shipway¹³ used Vinethene in combination with Tribromethanol in Amylene Hydrate and claimed that the combination had no evident (?) effect on the liver. He concluded, however, that "until further clinical experience has been gained, vinyl ether should not be used for periods longer than one hour and one half in view of the slight possibility of damage to the liver." This raises the general question of possible liver damage due to prolonged use of this anesthetic. Authors of most of the recent articles have all recommended its use for shorter anesthetizations. Of interest in this connection is the report of Ravdin and his associates¹². Forty-one of his patients received the anesthetic more than once apparently without deleterious effect. Twenty-three patients were anesthetized twice, ten three times, four four times and four more than four times.

Two deaths following the prolonged clinical use of Vinethene were noted by Goldschmidt,³ Bourne^{2d} reviewed these and added one from his own series. He felt that the liver changes present were not typical of liver necrosis resulting from anesthesia and therefore should not be attributed positively to the anesthetic. It must be noted that these patients received Vinethene for periods exceeding one and one-half hours, and that two of them were apparently poor anesthetic risks.

The consensus is that the optimum periods of anesthetization with Vinethene is not in excess of a half hour. Ravdin and his co-workers¹² point out the importance of volatilizing the anesthetic admixed with oxygen if it is to be used for periods exceeding one-half hour. This clinical recommendation confirms their experimental observations. The question of the method of administration also enters here. For the short anesthesia the open drop method is preferred and was used in 84 per cent of Ravdin's 2,675 cases, while the longer anesthetics require proper volatilization of the agent with oxygen as a precaution against liver damage. This is apparently easiest to maintain by the closed method.

Many authors have indicated the period of anesthesia, and it is interesting to note that some of the most favorable results have been reported with relatively short anesthetics. Ravdin's¹² series consisted of procedures that were practically all completed in less than thirty minutes. Connolly and Baker¹⁴ reported its use in dentistry for periods of from two to sixteen minutes and Goldman,¹⁵ also using it in dentistry, felt that it was satisfactory for this type of case.

Comparison with Ethyl Ether—Waters¹⁰ expressed the opinion that the induction and recovery occurring with new agents such as Vinethene should be compared with those occurring with nitrous oxide rather than with ethyl ether as has been done in this case. This would seem to be especially true with an agent intended for short procedures. Subsequently it was found by Ravdin and his co-workers¹² to be more rapid than nitrous oxide in induction and recovery. Molitor⁴ found rapidity of induction as compared with that of ether dependent on temperature but most clinical reports¹⁶ have noted rather consistent rapid induction as an advantage. It has been pointed out that rapid induction is related to the potency of this agent and can be safely accomplished only if the anesthetist is sufficiently familiar with the agent to appreciate the sudden depth of anesthesia which brings about this rapid induction. Over-concentration must be avoided and, since the usual eye signs are not reliable, rapid induction necessitates expert attention to the respiration if overconcentration is to be prevented. Ravdin recommends that the anesthetist exert caution lest he exceed the concentration in the blood necessary for surgical anesthesia. 18 mg per hundred cubic centimeters for general cases and 11 mg per hundred cubic centimeters for minor ones.

It may be granted that the action of Vinethene is characterized by rapid recovery, which does not involve any such potential danger as does the rapid induction. It has been reported by practically all the authors both experimentally and clinically.¹⁷ Molitor⁴ found that temperature of the product had no effect on rapidity of recovery experimentally.

Ravdin¹² pointed out that the period of excitement was considerably less than with ether. Dorfelf¹⁶ mentioned the infrequency of postanesthetic vomiting and Ravdin¹² claims that the incidence of untoward complications was low.

Field of Usefulness—Originally intended as a general anesthetic with the advantages of ether and ethylene, Vinethene has been principally recommended for use in certain limited fields, as pointed out by Tucker¹⁸.

Beach¹⁹ reported 2,632 cases including neurosurgical, ophthalmologic, otolaryngologic and gynecologic as well as cases in general and orthopedic surgery, dental surgery and obstetrics. He considers it acceptable in short cases in minor surgery only as a supplemental agent to nitrous oxide and ethylene where increased relaxation is desired in major surgery as an induction agent, in dental surgery and for short simple cases in the home or office, of the ambulatory type, and in cases where a gas machine is not available.

Connolly and Baker¹⁴ used it principally in dental surgery. The extensive series reported by Ravdin and his co-workers¹² were two fifths general and neurosurgical, two fifths otolaryngologic and one fifth dental, ophthalmologic and orthopedic. They recommended it for the extraction of teeth, reduction of fractures, manipulation of joints and a large number of surgical procedures which do not require prolonged anesthesia but which may require any degree of relaxation. Shipway¹³ at one time claimed that complete abdominal relaxation was not always obtained. Other workers, including Goldschmidt³ however, noted satisfactory relaxation. Goldman¹⁵ used it principally in dental surgery. Goldman employed a special apparatus which he designed for the administration of Vinethene. Connolly and Baker suggested that it be used as a substitute for nitrous oxide when the latter is not available.

Tucker¹⁸ noted that it was preferable to ethyl chloride or chloroform and recommended its use for short painful procedures, for short operations and occasionally to reinforce other anesthetic agents. Batzner¹⁶ concluded that for a wide variety of operative procedures of short duration Vinethene is a most useful anesthetic substance.

Obstetrics—Bourne^{2a} reported the use of Vinethene in 152 obstetric cases and later in an additional 500 cases.^{2d} He has always preferred the closed method of administration, but it must be remembered that many of his procedures exceed the half-hour period during which the open drop method appears to be preferable and, according to Bourne^{2e} and others¹⁴ relatively safe. The closed method has the advantage of conservation of the material. He^{2d} has determined the effects on the liver by the bromsulphalein test. He^{2e} has found that it does not depress muscle tonus in the intestine and uterus. He^{2e} declares that it has no effect on the coagulation time. He believes there is minimal danger to both mother and child with degrees of anesthesia which are adequate and sufficient for obstetric procedures. He^{2d} at first claimed that it was impossible to produce analgesia with Vinethene. Later he^{2e} used a mixture of 25 parts of Vinethene and 75 parts of ether for producing a satisfactory obstetric anesthesia. Tucker¹⁸ on the other hand does not believe that Vinethene should displace nitrous oxide in the long second stage labor case.

Other Observations—Ruth²⁰ reported one case in a series of ten in which evanosis and convulsions occurred. Anesthesia was completed with ethyl ether without mishap. Cyanosis was not observed and respiration did not cease in any of Goldman's¹⁵ short cases. None of his patients vomited or complained of nausea. Ravdin¹² did not encounter any com-

plications in his procedures—mostly of thirty minutes or less. Molitor⁴ and others have pointed out the importance of an adequate supply of oxygen. This, of course, refers especially to the closed technic used for periods longer than thirty minutes.

It has been claimed that the excess of mucus which occurs with Vinethene did not increase the evidence of pulmonary complications and that it ceases at the end of anesthesia, when it is vomited. The mucus as well as the vomited material might easily be inspired, resulting in pulmonary complications and therefore this factor may become more important when and if the anesthetic is used for longer periods.

It has been claimed that the safety of this agent is dependent on the ability and experience of the anesthetist¹⁸ and even that it should be used by the "physician-anesthetist" and not by the layman or general practitioner.

Age—Oehlcker²¹ found its use advantageous in small children, while Beach¹⁹ suggested its use in these patients with an ether follow on. The age range was 15 months to 75 years in Ravdin's¹² series of cases, while Goldman¹³ used it in those from 7 weeks to 65 years of age.

CONCLUSIONS

Although Ravdin¹² has pointed out that Vinethene falls short of an ideal substance possessing the pharmacologic and chemical characteristics of ether and ethylene, and although the present evidence does not indicate its use to replace ether or other agents in procedures exceeding one-half hour, it appears to be a useful anesthetic for short periods when given by an anesthetist familiar with the agent. The eye signs are not useful and the depth of anesthesia must be determined by the rate, depth, regularity and character of respiration. Cyanosis should not develop, if it does, oxygen should be administered and the procedure completed under other anesthetic agents. Rapid induction is an advantage of this agent provided over-concentration and excessive anesthesia are avoided. Rapid recovery is also an advantage.

For the present it is not recommended that the drug be used for periods exceeding one-half hour, and those employing it for any period should familiarize themselves with the nature of the compound.

As with any anesthetic agent, proper consideration should be given to age, cardiovascular disease, kidney disease, and especially pathologic conditions of the liver.

The Council voted to accept Vinethene-Merck for a period of one year for use as an anesthetic in short procedures and to publish this report at the time of acceptance.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

VINETHENE—Vinethenum—Vinyl Ether For Anesthesia—Merck— $\text{CH}_2\text{CHOCH}_2\text{CH}_3$ with the addition of 3.5 per cent absolute alcohol and 0.01 per cent of phenyl- α -naphthylamine.

Caution—Vinethene is inflammable and deteriorates on exposure. It is not to be used for anesthesia if the original container has been opened longer than twenty-four hours.

Actions and Uses—Vinethene is an inhalation anesthetic to be used for short anesthetics. It differs from ether, U. S. P., in the rapidity of its action. This property necessitates special caution in its administration. It is easy to pass from the level of surgical anesthesia to dangerous overdosage, therefore the importance of constant, close observation of the patient cannot be overemphasized. Properly watched this rapid action is of advantage in short anesthetics, as is the prompt recovery which follows administration of the drug.

The anesthetist should familiarize himself thoroughly with the properties of Vinethene before employing it. Of major importance is the fact that the eye signs usually depended on in anesthesia are entirely unreliable. The most important single signs to follow in determining the extent of the anesthesia are

the rate, depth, regularity and smoothness of respiration. If the anesthesia is administered in the proper way there should be no cyanosis and the development of such a condition is an indication for the employment of oxygen followed by the use of other anesthetic agents. Although there is usually an increased flow of saliva during maintenance, even when atropine is administered, postoperative complications have not been frequently encountered. Nausea and vomiting occur in about 5 per cent of cases.

Vinethene is intended primarily for use in minor surgical operations of short duration, and in dentistry. It has also been proposed as an induction anesthetic. It has been rather extensively used during labor and during postpartum obstetric procedures. It has, however, one major disadvantage when used in this branch of medicine—its rapid action has practically precluded its use for obtaining obstetric analgesia.

Under no circumstances should the anesthetic be pushed and if proper relaxation and anesthesia are not obtained with low concentrations other agents should be employed. In case of overdosage respiration is likely to be inhibited and anoxemia and cyanosis to develop. Under such circumstances the anesthetic must be discontinued and measures taken to stimulate the respiratory center and respiration. The explosive and fire hazards of Vinethene are just about equal to those of ether, U. S. P.

As with any other anesthetic agent, age, cardiovascular disease, renal insufficiency or hepatic damage, particularly the latter, must be given due consideration as contraindications. It may be administered by the open drop, semiofen drop or closed machine method. It would seem at the present time that the open drop method is preferable, for the short anesthetics.

Manufactured by Merck & Co. Inc. New York. U. S. patents 2,021,872 (Nov. 19, 1935, expires 1952), 2,044,800 (June 23, 1936, expires 1953), 2,044,801 (June 23, 1936, expires 1953). U. S. trademark 297370.

Vinethene occurs as a clear, colorless liquid with a slight purple fluorescence possessing a characteristic odor. It is miscible with methyl alcohol. Vinethene boils at 28.31°C.

Agitate 5 cc of vinethene in a small chilled glass stoppered cylinder with 2 cc of water previously boiled. The aqueous layer should not affect blue or red litmus paper.

Concentrate 10 cc of vinethene to about 1 cc, pour on clean odorless filter paper; no foreign odor becomes perceptible as the last portions disappear from the paper and the paper remains odorless.

Add 1 cc of cold vinethene to 0.5 cc of a cold solution of 1 Gm of silver nitrate dissolved in equal parts of 10 cc stronger ammonia water and 10 cc of water and 0.5 cc of a solution of 1 Gm of sodium hydroxide dissolved in 10 cc of water, cool in ice, shake for ten seconds, stopper with rubber stopper previously boiled with sodium hydroxide and allow to stand for thirty minutes; no deeper coloration should develop in thirty minutes than in a control prepared by using 1 cc of benzene previously washed with a 10 per cent solution of sodium hydroxide and 1 cc of an aqueous solution of 4 cc of $\frac{1}{4}$ mol of cobaltic chloride and $\frac{1}{4}$ mol of ferric chloride and 8 cc of $\frac{1}{4}$ mol of copper sulfate in 100 cc of water.

To 5 cc of vinethene add 1 cc of an alkaline solution of phenol prepared by dissolving 0.1 Gm of phenol in 20 per cent sodium hydroxide solution and diluting 1 volume with 24 volumes of water, stopper with a rubber stopper previously washed with sodium hydroxide and shake vigorously for three minutes; no darker color should develop than in a control using benzene and similar quantities of the reagent.

Evaporate 10 cc at room temperature dry at 50°C; the residue should not exceed 0.002 Gm.

PHYSIOLOGICAL SOLUTION OF SODIUM CHLORIDE—U. S. P. (See New and Nonofficial Remedies, 1937, p. 342)

The following dosage forms have been accepted:

Physiological Solution of Sodium Chloride 500 cc Bottle Prepared by the Abbott Laboratories, North Chicago, Ill.
Physiological Solution of Sodium Chloride 1000 cc Bottle Prepared by the Abbott Laboratories, North Chicago, Ill.

DEXTROSE (See New and Nonofficial Remedies, 1937, p. 155)

The following dosage forms have been accepted:
The Abbott Laboratories, North Chicago, Ill.

Dextrose 5% in Distilled Water. Each 100 cc contains dextrose U. S. P. 5.50 Gm. Supplied in bottles containing 500 and 1000 cc.
Dextrose 10% in Distilled Water. Each 100 cc contains dextrose U. S. P. 11 Gm. Supplied in bottles containing 500 and 1000 cc.
Dextrose 5% in Physiological Solution of Sodium Chloride. Each 100 cc contains dextrose U. S. P. 5.50 Gm and sodium chloride 0.85 Gm. Supplied in bottles containing 500 and 1000 cc.
Dextrose 10% in Physiological Solution of Sodium Chloride. Each 100 cc contains dextrose U. S. P. 11 Gm and sodium chloride 0.85 Gm. Supplied in bottles containing 500 and 1000 cc.
Dextrose 5% in Ringer's Solution. Each 100 cc contains dextrose U. S. P. 5.50 Gm, sodium chloride 0.7 Gm, potassium chloride 0.03 Gm and calcium chloride 0.025 Gm. Supplied in bottles containing 500 and 1000 cc.
Dextrose 5% in Lactate Ringer's Solution. Each 100 cc contains dextrose U. S. P. 5.50 Gm, lactic acid (as sodium lactate) 0.24 Gm, sodium chloride 0.69 Gm, potassium chloride 0.04 Gm and calcium chloride 0.02 Gm. Supplied in bottles containing 500 and 1000 cc.

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

THIRTY-SEVENTH ANNUAL PRESENTATION OF EDUCATIONAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The report presented herewith for the academic year 1936-1937 includes either statistical data or editorial comment regarding the medical schools approved¹ by the Council on Medical Education and Hospitals during this period. Also included are revised lists of hospitals approved by the Council for internships and residencies in specialties. The first revision of the lists of schools for physical therapy and clinical laboratory technicians which conform to the standards adopted by the American Medical Association likewise appears in this issue.

Figures are presented covering seventy-seven medical schools in the United States and ten in Canada, 712 hospitals approved for internships, 439 hospitals offering approved residencies in specialties, fourteen schools for physical therapy technicians and 125 schools for clinical laboratory technicians.

These data are based on official reports from the institutions listed. Acknowledgment is tendered the officers of the bodies mentioned and others for their ready cooperation in supplying the facts included in this presentation as well as for other material furnished throughout the year, enabling the Council to maintain its medical student and hospital registers efficiently.

PRELIMINARY EDUCATION

The minimum standard of preliminary education for approved schools of medicine since 1918 has been not less than two full academic years, including English, theoretical and practical courses in physics and biology and in general and organic chemistry, completed in institutions approved by accrediting associations acceptable to the Council. There are six such agencies, namely:

Association of American Universities
North Central Association of Colleges and Secondary Schools
Middle States Association of Colleges and Secondary Schools
New England Association of Colleges and Secondary Schools
Southern Association of Colleges and Secondary Schools
Northwest Association of Secondary and Higher Schools

The Council has published annually since 1915 a list of colleges of arts and sciences approved by these agencies as a guide to medical schools in the selection of students and also to assist the prospective medical student in choosing a college for his preliminary training. The compilation for the year 1936-1937 includes 764 colleges approved by the several bodies as follows:

Association of American Universities	282
North Central	275
Southern	230
Middle States	128
Northwest	63
New England	47

Of those recognized by the Association of American Universities, all but twenty-one are approved also by their district agency. In the various groups this dual approval of 261 institutions is distributed as indicated below:

North Central	102
Middle States	60
Southern	51
New England	29
Northwest	17

These five regional associations of colleges referred to cover among them the entire United States with the

exception of the far Southwest. Institutions in this territory can secure only the approval of the national group—the Association of American Universities.

Medical schools are privileged to accept applicants who have fulfilled the requirement in institutions not approved by the agencies mentioned, provided the applicant gives evidence of superior ability. Officials in selecting from the large number of applicants, however, give preference to those whose preparation has been received in institutions that are known to conform to

Chart 1

accepted standards. Of students from other institutions they exact, both qualitatively and quantitatively, a higher performance.

For the session 1937-1938, fifty medical schools in the United States have adopted preliminary requirements in excess of the minimum, i. e., five require a degree, thirty-nine require three years, one requires four years, four schools will admit students with three years of college work if the baccalaureate degree is conferred in absentia at the end of the first year in medicine, and one school has a requirement equivalent to two and one-half years. Twenty-seven schools exact the two year requirement. The general tendency toward a requirement of three or more years of college work seems to be due to two factors, first, a desire for more thorough grounding in all the branches of chemistry and, second, a desire for a greater familiarity with non-science sub-

(Continued on page 664)

¹ Including two schools whose approval has been withdrawn and two schools placed on probation. See footnotes to table 1, page 661.

[illegible]

(Continued from page 659)

jects, such as literature, history or economics, than can be secured in two college years. The medical schools in Canada also vary in their preliminary requirement. One requires a degree for admission to a five year course, four have a six year medical course preceded by senior matriculation which is equivalent to the work of the first year in a college of arts, one school requires one year for entrance to the five year medical course, three require two years, and one has a three year prerequisite.

The preliminary requirements for admission to the medical schools in the United States for 1936-1937 are shown in chart 1. In contrast, chart 2 records the training possessed by 5,718 freshmen enrolled during this period. More than half of the students (3,181) had a college degree before beginning medicine, and 27 per

Chart 2

cent had between three and four years, leaving 5 per cent with four years and only 12 per cent with the minimum requirement of two years.

Several medical schools which accept only those with three years of college work require that the bachelor's degree be conferred after completion of the freshman medical year. Therefore many more graduates hold the bachelor's degree than do entering freshmen. A table appears in this study recording the number of graduates of 1937 holding baccalaureate degrees (table 12). Similarly, mention is made of those who have received the degree of B.S. in medicine.

While the two year college prerequisite has been exacted by the Council for nineteen years, there are still eight states which have not revised or amended their statutes to conform, although these states, with possibly one or two exceptions, do not license other than graduates of approved schools. These states are California, Connecticut, Delaware, Massachusetts, Missouri, Nebraska, Ohio and Pennsylvania.

LENGTH OF MEDICAL COURSE

The medical course in the United States in general covers four calendar years of approximately thirty-two weeks each. Fifty-one schools offer such a course. The medical schools of the universities of Minnesota, Duke and Tennessee operate on the quarter plan, enabling the student by utilizing the summer months to complete the course in three calendar years. A good portion of the students of these schools do not elect to study during the summer months. The medical schools of the University of Chicago permit a student to progress as rapidly as he desires but here again, the majority of students complete twelve quarters of work. It may be said that actually fifty-five schools require a four year course, including two operated on the quarter plan and two by individualized instruction and the quarter system, while twelve, including one school operated on the quarter plan, require four years and a fifth year spent as an intern or in research work, the degree being conferred after completion of the internship. Duke University requires a two year internship. The internship requirement of the medical schools of the University of Chicago was discontinued in 1936. Ten schools offer only a two year course.

Five of the medical schools of Canada offer a five year course, four have a six year course and the University of Saskatchewan offers courses in the medical sciences only which are covered in two years. Four Canadian schools require an internship for graduation.

These data are included in table 1.

CURRICULUM

The curriculum to be covered in a course of four years in a medical school enjoying the Council's approval should consist of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours a year, and should be grouped as set forth in the following schedule, each group to be allotted approximately the percentage of hours of the whole number of hours in the courses is stated.

1	Anatomy including Embryology and Histology	14	— 18½%
2	Physiology	4½	— 6%
3	Biochemistry	3½	— 4½%
4	Pathology Bacteriology and Immunology	10	— 13%
5	Pharmacology	4	— 5%
6	Preventive Medicine and Hygiene	3	— 4%
7	General Medicine	20	— 26½%
	Neurology and Psychiatry		
	Pediatrics		
	Dermatology and Syphilis		
8	General Surgery	13	— 17½%
	Orthopedic Surgery		
	Urology		
	Ophthalmology		
	Otolaryngology		
	Röntgenology		
9	Obstetrics and Gynecology	4	— 5%
	Total	76	— 100%
	Electives	24	— 0%

When the teaching conditions make it desirable a subject may be transferred from one division to another.

SCHOOLS OF THE BASIC MEDICAL SCIENCES

Facts revealed by the recent medical school survey led to the preparation and adoption by the Council, at its meeting on Feb. 14, 1937, of the following statement concerning schools that do not offer a complete course. The statement as originally prepared did not include the word "Basic," this being added after further consideration by the Council at its meeting in May.

SCHOOLS OF THE BASIC MEDICAL SCIENCES

Following the recent survey of the medical schools it was decided that effective July 1, 1939, the Council will publish a list of schools which teach acceptably gross and microscopic

anatomy, biochemistry, physiology, pharmacology, bacteriology and pathology, even though they do not offer a full course leading to a medical degree.

The acceptance of courses involving the use of clinical material shall be left to the discretion of the faculties which admit to advanced standing students transferring from approved schools of the medical sciences.

Surveys of the clinical courses and facilities will be made by the Council and reported to the individual medical schools on request.

STATISTICS OF MEDICAL SCHOOLS

Table 1, pages 660 and 661, lists the medical schools in the United States and Canada approved by the Council on Medical Education and Hospitals of the American Medical Association during 1936-1937 and contains figures regarding the premedical requirement for the session 1937-1938, length of the medical course by year, enrolment by classes for the session 1936-1937, including fifth year students interning or engaged in research, the number of graduates since July 1, 1936, dates of the beginning and ending of the forthcoming session, and the month until which applications for admission to the freshman class are received. Changes in the classification that have taken place since the publication of the educational statistics in 1936² can be noted in the footnotes at the bottom of the table and refer to those schools which are marked by asterisks preceding the name. Also contained in the footnotes are references to the fifth and sixth year enrolments and those schools which admit students at varying times during the year. The two medical schools of the University of Chicago do not report their students by classes and in this tabulation, therefore, only the total enrolment is given.

The data presented in this table constitute the basis also for several of the subsequent tabulations. Beginning on page 676 are given historical information and essential facts concerning the schools arranged by states.

Seventy-seven institutions in the United States and ten in Canada are listed. With the exception of four, all these schools at the present time enjoy the full approval of the Council. In eighty-five schools 6,564 freshman students were enrolled, 5,858 sophomores, 5,688 juniors, 5,673 seniors, 384 fifth year and 246 sixth year students, during the session just ended. In the two medical schools of the University of Chicago 618 students were enrolled, making a total of 25,031 in the eighty-seven schools listed. There were in the United States 5,910 freshmen, 5,269 sophomores, 5,140 juniors, 5,158 seniors and the 618 students of the University of Chicago, a total of 22,095. The total students registered by classes in the United States was 21,477. The enrolment in the ten Canadian schools was first year 654, second year 589, third year 548, fourth year 515, fifth year 384 and sixth year 246, a total of 2,936. The 25,031 medical students enrolled do not include 1,255 in the United States and 131 in Canada interning as a requirement for the degree of Doctor of Medicine.

Since July 1, 1936, 5,885 received M.D. degrees, 5,377 from schools in the United States and 508 from Canadian institutions.

In addition there were 216 part-time, 288 special and 671 graduate students studying in medical schools.

Eleven medical schools had an enrolment of less than 100 students. None of the schools comprising this figure give the complete medical course. Thirteen schools matriculated fewer than 200 but more than 100, twenty-eight less than 300, fourteen fewer than 400 and 500 respectively, and five less than 600. Two schools matriculated more than 600. The smallest enrolment (twenty)

was at the University of Mississippi School of Medicine, which for the session 1935-1936 did not offer instruction to freshmen and consequently had no sophomore class during 1936-1937. This school does not offer the complete course. The greatest number (834) were enrolled in the University of Toronto Faculty of Medicine, which has a six year course including premedical subjects. The corresponding high figure among schools in the United States was 646 at the University of Illinois College of Medicine. The lowest enrolment among four year medical colleges in the United States was 100 at Albany Medical College. This school likewise awarded M.D. degrees to the smallest group (twenty-one) since July 1, 1936. The school graduating the greatest number was Rush Medical College, which awarded 289 diplomas. This is a far greater figure than in previous years, owing to the discontinuance of the requirement of an internship for the degree and the subsequent issuance of a diploma to those who ordinarily would have received it following the internship and those who profited by the discontinuance of the requirement. The majority of schools will begin the session 1937-1938 about the middle of September and end early in June.

Of sixty-seven schools that replied to the inquiry regarding the month until which applications for admission to the first year class will be received, one replied January, two February, twelve March, nine April, four May, twelve June, four July, five August, seventeen September, and one November.

The name of the dean or administrative officer of each institution is also given in table 1.

BIRTHPLACE OF STUDENTS

In table 2, pages 662 and 663, the birth state of students in attendance in medical schools during 1936-1937 is shown by schools. The state furnishing the greatest number of students, according to state of birth, was New York with 3,226, followed by Pennsylvania with 1,985, Illinois with 1,566 and Ohio with 1,176.

From the twelve states in which no medical schools are located there were enrolled as students the following:

	Number Enrolled	Number of Schools
Arizona	38	22
Delaware	41	14
Florida	133	16
Idaho	90	33
Maine	113	35
Montana	95	34
Nevada	26	15
New Jersey	838	66
New Mexico	69	23
Rhode Island	119	39
Washington	251	44
Wyoming	29	16

There were 140 born in the United States territories and possessions studying in thirty-nine schools in the United States and four in Canada. In addition, 2,580 students of Canadian birth were also studying medicine, 131 of whom were matriculated in forty-two schools in the United States and 2,449 in the ten Canadian medical schools.

The medical school enrolment is further classified by birthplace in table 3, indicating that 14,405 are studying in the state of their birth and 10,626 elsewhere. This is particularly significant in Illinois, where, of the 2,306 students in five schools, 1,121 were born outside the state. More than 900 born elsewhere are studying in Pennsylvania. Altogether, 42.5 per cent are studying in schools located in other than their birth state. Eliminating the 1,842 born in states having no medical school, there are still 8,784 of the total number of students, 25,031, studying outside their birth state.

A perusal of table 3 will show many instances wherein the number studying elsewhere far exceeds the number attending school in the state of birth. It also shows some states in which the contrary is the case, notably Arkansas, Georgia, Indiana, Iowa, Kansas, Minnesota, Ohio, South Carolina and Texas. Of those enrolled in medical schools in Canada, 2,449 were born in Canada, while 487 were born elsewhere.

It is conceded that this tabulation does not present an absolutely true picture in that all those studying in schools located in states other than their birthplace cannot be classed as nonresidents, since they may have

TABLE 3—Students Classified by Birthplace

State	Number of Schools	Attending School in State of Birth	Birthplace Elsewhere

established their homes in other states. It is believed, however, that the table reveals a trend which may be of interest.

RESIDENT AND NONRESIDENT STUDENTS

Table 4, presented for the first time this year, gives for each medical school the number of resident and nonresident students according to the individual school's definition of the word "resident." Among state universities, as well as other schools, there is a variation in the definition of the term. In some universities this is determined by the legal or permanent residence of the student, parents or guardian only, while in some schools continuous residence for six months, one, two or three years just prior to the student's application for enrollment is also required. Others require the student to be a voter, parents' home in the state established prior to beginning of premedical work, the student is a taxpayer or a dependent of a taxpayer, regardless of whether he resides in the state, self-supporting student, and each case determined by attorney after consideration of birth, citizenship, residence of parents, and so on. Of these methods the most common is the determination of residence by ascertaining whether the student, parents or guardian has been a bona fide resident for a period not less than six months. This is in force in sixteen universities. In most schools also a student coming into

the state for educational purposes only and establishing residence would not be considered a resident. Among other than state universities the term "resident" is defined mostly by the home address of the student or the legal residence of the parents or guardian. Two such schools did not reply to our inquiry, while in one school a student is considered a resident if he lives in the state.

TABLE 4—Resident and Nonresident Students

University of Wisconsin	281	19	299
Marquette University	163	145	308
Totals	14,026	8,069	22,095

On the basis of these factors, in the seventy-seven approved medical schools in the United States there were 14,026 students reported as residents and 8,069 as nonresidents, a total of 22,095 in the United States. The state university enrolling the greatest number of nonresidents was the University of Maryland College of Physicians and Surgeons, which has 240 residents and 153 nonresidents, while Ohio State University Col-

lege of Medicine and the University of Texas School of Medicine did not register any nonresidents, and only two of the 646 students of the University of Illinois College of Medicine were nonresidents.

Among other than state universities it is of interest to note the resident and nonresident enrolment. Many of the schools draw their enrolment from residents of

TABLE 5—Schools, Students and Graduates by States*

* Excluding fifth or intern year students

the state. This is particularly true at Southern California, Stanford, Emory, Wayne, Long Island, Buffalo, New York Medical College, New York University, Syracuse, Cincinnati, Western Reserve, Pittsburgh and Baylor.

There is a similarity between the figures in this table and those of the preceding one classifying students by birthplace. Excluding the Canadian registration given in table 3, there were 11,956 students attending school in the state of their birth and 10,139 elsewhere, as compared with 14,026 whose legal residence is in the state in which they are pursuing their medical courses and 8,069 classified as nonresidents.

The ten schools in Canada reported 2,127 residents of Canada and 809 nonresidents. Their definition of a resident varied from students whose permanent address is within one of the provinces of Canada or the specific province in which the school is located to home address on registration, and taxpayers. The greatest number of nonresidents in any one school were enrolled at McGill (355), while only 128 residents of Canada were studying. This school has always obtained the major portion of its student body from the United States. All other institutions registered fewer than 100 nonresidents but more than twenty-five with one exception—the University of Saskatchewan—with only two out of an enrolment of fifty.

Comparing these figures with those in table 3, classifying birthplace reveals as in the United States, somewhat similar figures—2,449 born in Canada and 487 elsewhere, compared with 2,127 residents and 809 nonresidents.

SCHOOLS, STUDENTS AND GRADUATES BY STATES

The number of schools, students and graduates for each state are given in table 5. New York, with the largest number of schools, nine, naturally had the greatest number of students and graduates, 2,562 and 628 respectively. Pennsylvania with six schools, 2,344 students and 594 graduates, Illinois with five schools, 2,306 students and 741 graduates ranks in the third largest group, while Massachusetts with three schools, 1,192 students and 312 graduates and California with four schools, 1,093 students and 226 graduates complete the group of states having a medical school enrolment over 1,000. In the seventy-seven medical schools in the United States, including those that offer only preclinical courses, there were 22,095 students and 5,377 graduates. Students entering as a requirement for the degree, or fifth year students, are not included in the figure 22,095. Also excluded are part-time, special and graduate students.

The greatest number of graduates in any one state were the 741 who completed their courses in Illinois schools. New York with four more schools than Illinois had 113 fewer graduates and Pennsylvania with one more school had 147 fewer graduates than Illinois and thirty-four fewer than New York.

REQUIRED HOSPITAL INTERNSHIPS

The medical schools and licensing boards now requiring a hospital internship for the M.D. degree and state licensure, respectively, are shown in tables 6 and 7.

Oklahoma	1923	Wyoming	1921

A few of the medical schools will accept research or other clinical work in lieu of the internships. Thirteen schools in the United States and four in Canada exact the internship requisite. Since 1915 the M.D. degree at the University of Minnesota Medical School has been conditioned on an internship. Rush Medical College, which has required the internship for the M.D. degree since 1919 and the School of Medicine of the Division of the Biological Sciences, University of Chicago, since

1930, discontinued this formal requirement in 1936. However, as will be noted elsewhere in these statistics, 272 of the 359 graduates of these schools had or were required to serve an internship before being awarded the degree. McGill University Faculty of Medicine

Completed medical course. Internship or other acceptable clinical work is a requirement for the M.D. degree.

* Internship as a requirement for the degree discontinued in 1936.

† Two year internship requirement after graduation.

reorganized its medical curriculum into a course of five years, including an internship replacing the former course spread over five academic years of seven and a half months each by a course covering four years of nine months. The fifth year may be spent in an internship in an approved hospital or in further medical study

at McGill or at another medical school approved by it. The changed curriculum was inaugurated for the freshman class of 1936-1937. It will not affect the students who began their course under the former system.

Duke University School of Medicine grants the degree after the completion of the senior year, but all graduates are required to spend at least two years in hospital or laboratory work after graduation.

As revealed in table 7, eighteen states, Alaska and the District of Columbia require that applicants for licensure possess a hospital internship. The first state exacting this requirement was Pennsylvania in 1914 and the last one New Hampshire, which becomes effective Jan. 1, 1938.

While some of the medical schools and licensing boards may have their own list of hospitals recommended for intern training, generally the Council's list of hospitals approved for internships is followed. A revised edition will be found beginning on page 683.

During 1936-1937 there were 1,255 students of the United States and 131 in Canada reported as interning, a total of 1,386.

GRADUATES AND INTERNSHIPS

In table 8 are enumerated the graduates of the United States and Canada from July 1, 1935, to July 1, 1936, who were serving internships during all or part of the period from July 1, 1936, to July 1, 1937. Included also are figures for those schools which require the internship or other acceptable clinical work as a requirement for graduation. There were 5,484 fifth year students or graduates serving internships during the period July 1, 1936, to July 1, 1937. The number of graduates and those who completed the medical course during the period July 1, 1935, to July 1, 1936, was 5,836, 4,314 graduates of four year medical schools and 1,522 fifth year students. Of the figure 5,836, 352 either were not successful in securing or did not desire internships. Several of the fifth year students satisfied this requirement by research or other clinical work. These 4,314 graduates and 1,522 intern students represented 3,965 graduates and 1,391 intern students of the United States and 349 graduates and 131 intern students in Canada. In the Canadian schools, of the 480 graduates or intern students, 441 were serving internships and thirty-nine are unaccounted for. In the United States there were 5,356 graduates or students, of whom 5,043 were interning, leaving 313 not serving internships during this period.

Of the 5,484 interns, 1,391 in the United States and 131 in Canada were fulfilling the intern requirement for the M.D. degree, a total of 1,522.

With the exception of four, every school in the list has more than 90 per cent of its graduates serving internships, and in thirty-seven schools 100 per cent interned. Excluding those schools that require the internship for graduation, 91.8 per cent of all graduates here listed have or are obtaining this added experience.

The two medical schools of the University of Chicago discontinued the internship requirement in 1936 and in consequence many of those who received the M.D. degree since July 1, 1936, did not serve an internship as a requisite for the degree, although many are interning. For purposes of this table it was necessary to include in the first column both those who received the M.D. degrees with and without an internship since July 1, 1936, since a similar table published in 1936 included those who were classified as intern students up to July 1, 1936, and only in this way could those interning during 1936-1937 be recorded.

WOMEN IN MEDICINE IN THE UNITED STATES

During the past year there were 1,113 women studying medicine, twenty less than during the session 1935-1936. The percentage of women to all students for the academic year 1936-1937 was 5.1. There were 238 graduates, eight less than last year. Of the women matriculants, 107 were in attendance at the one medical college for women, while 1,006 were matriculated in sixty-eight coeducational schools. From the Woman's Medical College twenty-three were graduated, while 215

TABLE 9—Women in Medicine in the United States

Year	Women Students	Percentage of All Students	Women Graduates	Percentage of All Graduates
1903	1 073	4.1	210	4.0
1910	907	4.0	116	2.6
1913	592	4.0	92	2.6

1930	935	4.4	204	4.5
1931	990	4.5	217	4.6
1932	955	4.3	208	4.2
1933	1 056	4.7	214	4.4
1934	1 020	4.5	211	4.2
1935	1 077	4.7	207	4.1
1936	1 133	5.0	246	4.7
1937	1 113	5.1	238	4.4

secured their degrees from coeducational institutions. These data are given in table 9. Of interest also is the fact that eleven schools enrolled more than twenty-five women. In the thirteen years since 1925, 2,771 women have graduated in medicine.

DISTRIBUTION BY SEX

Students and graduates in the United States and Canada classified by sex are shown in table 10. There were seventy-six schools which had both men and women students in the United States and Canada, of which sixty-two had women graduates. At the one medical school for women, the Woman's Medical College of Pennsylvania, 107 students were enrolled and twenty-three graduated. Eight of the eleven schools in the United States and Canada which do not offer the complete course also had women students. Altogether there were 23,787 men and 1,244 women students, and 5,624 men and 261 women graduates. Of these 20,982 male students and 5,139 graduates were in the schools in the United States and 2,805 and 485 respectively in Canada. Likewise there were 1,244 women students and 261 graduates in the United States and Canada respectively. Of the 23,787 and 5,624 male students and graduates, 3,804 and 692 respectively were enrolled in schools in the United States which are not coeducational or do not admit women, and 294 and 47 respectively in Canada. An average of fourteen women students were enrolled in the seventy-six coeducational institutions in the United States and Canada. There was an average of four graduates from sixty-two schools.

PART-TIME, GRADUATE AND SPECIAL STUDENTS

In fifty-one medical schools of the United States and three in Canada there were in addition to the regular, enrolled students 1,175 part-time special and graduate students pursuing medical subjects. This group consists of 216 part-time, 288 special and 671 graduate students.

The part-time students were enrolled in thirty schools, the greatest number (forty-two) were enrolled at the

University of Minnesota Medical School. Twenty-three were at the University of Southern California School of Medicine, the medical schools of the Universities of Arkansas, Kansas, Wayne and St. Louis University.

had between ten and seventeen, while the remainder had less than eight.

Of the special students, the greatest number (eighty-three) were at Northwestern University Medical School, at the School of Medicine of the Division of Biological

Sciences of the University of Chicago there were forty-five, and at the University of Toronto Faculty of Medicine twenty-four. The 288 special students represented thirty-three schools. Twenty of these schools had no part-time matriculants.

Students pursuing subjects leading to higher degrees were studying in twenty-seven schools. Altogether there were 671 such, of whom more than sixty were studying in each of six schools, the greatest number (ninety) having been enrolled at the University of Illinois College of Medicine.

Total	216	233	671

The following schools matriculated these three types of students: Universities of Southern California, Indiana, Kansas, Johns Hopkins, Michigan, Buffalo, New York University and Toronto.

Among Canadian schools only six part-time, twenty-nine special and forty-two graduate students were enrolled.

These data will be found in table 11.

GRADUATES WITH BACCALAUREATE DEGREES

From the figures contained in table 12, it can be noted that 3,863 of the 5,885 graduates of medical schools during 1936-1937 also hold baccalaureate degrees. Fig-

ures are not readily available to show how many of these graduates obtained their degrees subsequent to beginning the medical course. Only four schools in the

Totals	5,885	3,863

Estimated figure

United States required a degree for admission for the session 1936-1937 one required four years, thirty-six required three years, three schools admitted students with three years of college work provided the

baccalaureate degree would be conferred in absentia at the end of the first year in medicine, thirty-two exacted the two year requirement and one the equivalent of two and a half years. Twenty-five schools offer a B S in medicine degree at some time during the medical course—five at the end of the first year, sixteen after two years in medicine, and two each after three and four years respectively. All the graduates of Stanford, Johns Hopkins, Wayne, Albany, Cornell, New York University, Western Reserve, Oregon, Jefferson and Vanderbilt held baccalaureate degrees. Three of these schools—Stanford, Wayne and Oregon—do not have a degree requisite.

SCHOOLS STUDENTS AND GRADUATES IN THE UNITED STATES 1905-1937

The number of medical schools, students and graduates in the United States for each five year period from 1905 to 1920, and for each year since is shown in table 13. The total number of undergraduate medical students for the college session 1936-1937 was 22,095, a decrease of 469 from the preceding session. In 1905 in the 160 schools then existing there were 26,147 students. This tabulation includes data for only those taking medical courses leading to the M D degree. They do not include part-time and special students even though their work may later be accepted for the M D degree, since at the time they are reported as part-time and special students and not candidates for a medical degree. Omitted from these figures also are university graduate students majoring in the medical school but not candidates for the M D degree. In the ten years from 1910 to 1920 there was a steady decrease in the

TABLE 13—Schools Students and Graduates in the United States—1905-1937

Year	No Schools	Students*	Graduates

1936	77	22 564	5 163
1937	77	22 095	5 377

* Includes figures for schools offering preclinical courses

enrollment, while from 1921 to 1935 there was a continuous increase. In 1936 the enrollment decreased by 324 from the preceding year and in 1937 it dropped 469. Two years ago the Council issued a warning against the admission of larger classes than can be accommodated or than can reasonably be expected to satisfy approved scholastic standards. Many of the schools heeded this declaration and decreased their freshmen enrollment in the interest of better medical education and others are planning to do so in the future.

Again referring to table 13, it will be noted that the total number of graduates was 5 377, an increase of 194 over the year 1936. With the exception of the slight decrease in the number of graduates in 1933, as com-

pared with the previous years, there has been a steady increase since 1926. There were marked increases in 1923, 1924 and 1925. In the seventy-seven recognized medical schools in the United States during 1936-1937 there were 22,095 students, including those having an incomplete course, and 5,377 graduates.

STUDENTS BY CLASSES—1930-1937

The total number of students in the various classes of the medical schools in the United States for each session from 1930-1931 to 1936-1937 inclusive is shown in table 14. The total attendance for the first year for the session 1936-1937 was 5,910, ninety-five fewer than the number enrolled for the session 1935-1936. Since the session 1933-1934, when there were 6,457

TABLE 14—Students in the United States Shown by Classes—1930-1937

* Enrollment for the two medical schools of the University of Chicago not included

† Enrollment for the two medical schools of the University of Chicago and Duke University not included

‡ Intern year

enrolled, there has been a reduction in this class of 547. The total attendance for 1936-1937 for the remainder of the classes was respectively 5,269, 5,140, 5,158 and 1,255, a total of 23,350. The two medical schools of the University of Chicago are not operated under the promotion by class system but on an individual plan. It is not possible for the schools to report their students in this manner and accordingly they are not included in the figures by classes, but their enrollment is included in the total. At the School of Medicine of the Division of Biological Sciences of the University of Chicago there were 294 students enrolled and 324 at Rush Medical College, a total of 618. There were 427 fewer students enrolled than in 1935-1936, 771 fewer than 1934-1935, but 343 more than were enrolled in 1930-1931. The sophomore enrollment decreased 189 and the junior enrollment ninety, but there was an increase of 138 in the senior enrollment as well as in the fifth or intern year students (forty-two). These figures are exclusive of the figures for the two schools referred to.

The Association of American Medical Colleges³ reports that there were 35,439 applications for admission to the 1936 freshman class, representing 12,192 applicants, and of these 6,465 were accepted and 5,727 rejected. However, the actual freshman enrollment was 5,910 exclusive of the two Chicago schools. It will be noted that including the new matriculants of the University of Chicago, 649 were accepted by medical schools who did not enroll either because of multiple application or did not remain in medical school a sufficient length of time to be reported at the end of the year as having been members of the class.

NEGRO STUDENTS AND GRADUATES

The Negro medical students for the session 1936-1937 enrolled in the United States and Canada are recorded by classes in table 15. Totals for the college session 1935-1936 are shown for comparison. There were 372

such students and eighty-four graduates, an increase of three and eleven, respectively. The only medical school strictly for Negro youth, Meharry Medical College matriculated 200 students and had thirty-five graduates. At Howard University College of Medicine they comprise a majority of those in attendance, and for this session 126 students of the class of 135 and the thirty-five graduates were Negroes. These two schools graduated the majority of the Negro students. All other schools (eleven) graduated a total of fourteen. In twenty schools in the United States, exclusive of Meharry and Howard, forty students were enrolled. There were six Negro students in three Canadian schools and in one there were two graduates. The enrolment by classes in all schools was first year 130, second year 88, third year 70 and fourth year 82, a total of 372. In 1935-1936 corresponding figures were 107, 98, 84 and 78, a total of 369. The freshman enrolment increased twenty-three, the sophomore class decreased ten, the junior class decreased fourteen and the senior class increased four.

FEES

In table 16 the eighty-seven medical schools of the United States and Canada have been grouped according to the tuition fees charged. To arrive at the figures listed, an average was computed of the resident fees for each school. Included in these fees are the various minor charges, such as for matriculation, breakage, diploma and graduation. Four schools have fees of less than \$100. These were Louisiana State University, University of North Dakota, University of Oklahoma and the University of Texas. The eleven schools having fees over \$500 are Yale, George Washington, Johns Hopkins, Columbia, Cornell, Long Island, New York Medical College, New York University, Syracuse, Buffalo and Pennsylvania. Thirty schools in the United States and three in Canada made an additional charge for nonresidents ranging from \$50 by the Universities

of Mississippi, Missouri, Cincinnati (nonresidents of Cincinnati) and Virginia to \$300 exacted by the University of California and Louisiana State University.

Fees charged for the session 1936-1937 as compared with the session 1935-1936 remained the same with one exception, i. e., a school in the \$100 to \$200 group was raised to the \$200 to \$300 group.

TABLE 16—Fees, 1936-1937—United States and Canada*

	Schools
Under \$100	4
\$100 to 200	9
200 to 300	27
300 to 400	15
400 to 500	21
500 or over	11
Total	87

* Based on fees charged resident students

The lowest nonresident fee was charged by the University of Kansas (\$42 for the first year, \$60 for the second year and \$87 for the third and fourth years). Thirteen schools have a nonresident fee of \$100 or less, fourteen schools between \$100 and \$200, and six schools between \$200 and \$300. The data and text regarding table 4 listing the number of residents and nonresidents and the definition of the term resident may be of interest in connection with the fees charged nonresidents. The fees are not listed in these statistics by individual schools other than in the descriptions beginning on page 676.

The average resident fee charged all schools was \$334.

AVERAGE AGE OF GRADUATES—1937

In table 17 is shown the average age of the students graduating this year from each of the four year medical schools in the United States, and those schools offering a five year course, the fifth year of which is an internship. The average age of the 5,377 graduates was found to be 26.5 years. The school with the highest average (twenty-nine) was Meharry Medical College, three schools had an average of twenty-eight or more but less than twenty-nine, for fifteen schools the average was twenty-seven or twenty-seven and some tenth, twenty-seven had a score of twenty-six years or more but less than twenty-seven, and twenty-one schools ranked below twenty-six, the lowest of which was 24.9 years. One might suppose that the premedical requirement is a factor in the age variance, but in reality, as shown in table 12, 3,622 of these graduates had baccalaureate degrees most of which were obtained before entering medical school. At the bottom of the table are included the total number of graduates at each age, ranging from one who graduated at twenty-one years to 114 at thirty-five years or over.

Twenty-two and four tenths of all graduates attained the age of 25, the next highest figure, 1,161, 21.6 per cent, was 26 years. Six per cent graduated at 22 years and nine per cent at 34 years.

The averages in comparison with investigations made in previous years are given as follows:

1916	26.5
1922	26.8
1925	26.8
1928	26.8
1937	26.5

As will be noted, there has been very little difference in the average age over a period of twenty-one years,

and the age of the majority of graduates can safely be estimated at from 25 to 27 years

CITIZENS OF THE UNITED STATES ENROLLED IN FACULTIES OF MEDICINE ABROAD

A study of the number of citizens of the United States pursuing medical courses in faculties of medicine abroad has been carried on by the Council since 1931, when it became evident that great numbers were going

to Europe to study. Table 18 lists the institutions in which such students are enrolled. This tabulation covers the academic year 1936-1937. In a few cases because figures were not available it was necessary to reproduce figures from previous sessions for several schools known to have citizens of the United States enrolled. Including these figures there were 1,618 students and 509 graduates or those who completed their training in ninety-five institutions—eighty-nine schools in seven-

teen European countries, two in two South American countries and four in three countries of Asia. The files of the Association of American Medical Colleges indicate that the application record of many of these students show that they have made application to medical schools in the United States without success. A study is also being carried on of the license record of foreign physicians.⁴

credentials, which are equivalent to licensure in this country. In 1936, 237 were so registered. While this table makes no differentiation between United States citizens and those foreign born, it can be assumed that the increasing number of those seeking licensure represent to a great extent United States students who migrated to European and other countries. In 1933 the Federation of State Medical Boards adopted a resolu-

* 1933-1936 figures ** 1934-1935 figures *** 1933-1934 figures

Table 19, recording the number of graduates of foreign medical faculties (representing both American and foreign born physicians) examined by licensing boards in the United States in six years and the percentage failing, is of interest. In addition to the figures given, a number have been periodically licensed in New York without examination—by endorsement of their foreign

tion to the effect that no student matriculating in a European medical school subsequent to the academic year 1932-1933 will be admitted to any state medical licensing examination who does not present satisfactory evidence of premedical education equivalent to the requirements of the Association of American Medical Colleges and the Council on Medical Education and Hospitals, and graduation from a European medical

he is graduated is located. This policy of the federation has been made effective by individual action on the part of many of the state licensing bodies and the National Board of Medical Examiners.

The House of Delegates of the American Medical Association in 1936 endorsed a resolution urging that graduates of medical faculties of other countries be expected to prove their fitness for medical practice by being in possession of a license to practice in the country of their graduation and a certificate of internship in a hospital approved for such training or complete the fourth year in an American class A medical school. It is to be hoped that those being admitted to practice have such qualifications.

Further, hospitals in which these students seek internships in order to maintain approval by the Council may accept them on the successful completion of parts I and II of the examinations of the National Board of Medical Examiners, provided suitable graduates of American schools are not available.

The enrolment of students in foreign countries for each session since 1930-1931 is shown in table 20. The largest numbers were enrolled in Austria, Germany,

Further, in 1934 the Federation of State Medical Boards passed a resolution recommending to its constituent boards that until adequate information is available, these boards deny graduates of foreign medical schools admission to the licensure examination. The Federation's rulings have not been particularly effective. However, while over 600 secured licenses to practice medicine during 1936 in thirty states, 454 were registered in New York.

Several years ago the governments of many European countries sent representatives to this country to discuss appropriate measures for dealing with students from the United States. By the raising of entrance requirements, reduction in enrolment and careful scrutiny of credentials, the number studying abroad is gradually being reduced. Many are no longer accepting new students.

Italy, Scotland and Switzerland. The greatest number (227) in any one school was the enrolment in the School of Medicine of the Royal Colleges, Edinburgh, followed by the University of Vienna with 166 and the University of Rome with 128. Fifty-four schools had less than five students. Statistics presented in the State Board Number of THE JOURNAL indicate that in a five year period 31.5 per cent of those examined who were graduates of the University of Vienna failed and the University of Rome had 53.6 per cent failures. Completion of the course at the School of Medicine of the Royal Colleges does not qualify the student for practice. He is required to be in possession of the certificate of one of the licensing corporations of Great Britain. It is not known what standing they might have before licensing boards in this country.

DESCRIPTION OF MEDICAL COLLEGES

ALABAMA

University (Tuscaloosa)

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868 inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907 when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. Coeducational since 1920. Minimum entrance requirements are ninety semester hours of collegiate work. The course of study covers two years of thirty-six weeks each. The faculty includes 15 professors and 12 instructors, assistants, etc., a total of 27. The tuition fees are \$271 each year. Each class is limited to fifty students. The registration for 1936-1937 was 87. The next session begins Sept 8 1937 and ends May 24 1938. The Dean is Stuart Graves, M.D.

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE 300 West Markham Street—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 27 professors and 67 lecturers and assistants, total 94. The curriculum covers four years of nine months each. Entrance requirements are two years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The fees for the four years for residents or Arkansas are \$275; nonresidents are charged \$200 additional each year. The registration for 1936-1937 was 298 graduates, 61. The next session begins Sept 29 1937 and ends June 7 1938. The Dean is Frank Vinsonhaler, M.D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL University Campus Berkeley Medical Center San Francisco—Organized in 1862 as the Toland Medical College. The first class graduated in 1864. In 1872 it became the Medical Department of the University of California. In 1909 by legislative enactment the College of Medicine of the University of Southern California at Los Angeles became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged and elective chairs in homeopathic materia medica and therapeutics were provided. Coeducational since organization. Three years of collegiate work is required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The faculty is composed of 152 professors and 238 associates and assistants, a total of 390. The course covers four years of eight months each and an additional fifth year consisting of an internship in a hospital or of special work in a department of the medical school. Fees for the four years respectively, for residents of California are \$277 \$240 \$235 and \$235; nonresidents are charged \$300 additional each year. The registration for 1936-1937 was 247, graduates 47. The next session begins Aug 23 1937 and ends May 21 1938. The Dean is Langley Porter, M.D. San Francisco.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda, the clinical departments at Los Angeles. Coeducational since organization. The faculty is composed of fifty professors and 269 associates, assistants and instructors, a total of 319. The course covers a period of five years including one year of internship. During the second year the students are in school twelve months. This is accomplished by means of the cooperative plan, the student spending alternate months in an approved hospital in practical lines of medical training. The first third and fourth years each cover ten months of continuous school work. Sixty-four semester hours of collegiate work are required for admission. The total fees for the four years respectively are \$470 \$375 \$470 and \$480. The registration for 1936-1937 was 421 graduates, 80. The next session begins September 1 1937 and ends June 12 1938. The Dean is E. H. Risley, M.D. Loma Linda and the Associate Dean is W. E. Macpherson, M.D. Los Angeles.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE 3551 University Avenue—Organized in 1885 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Medical Department of the University of California in Los Angeles. In 1909 the College of Physicians and Surgeons established in 1904 became the Medical Department of the University of Southern California. Its activities were suspended in 1920, reorganized in May 1928 under present title. The faculty consists of 139 professors and 139 instructors, assistants and others, a total of 278. An internship is required for graduation. Three years of collegiate work is required for admission. Coeducational since organization. Annual fees amount to \$450. The registration for 1936-1937 was 187 graduates, 46. The next session begins Sept 20 1937 and ends June 4 1938. The Dean is Paul S. McElbreen, Ph.D.

San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE 2398 Sacramento Street San Francisco—Organized in 1908 when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 171 professors and 146 lecturers, assistants and others, a total of 267. Three years of collegiate work is required for admission. The course covers four years of eight and one-half months each plus a fifth year of intern work. The fees for the four years respectively are \$470 \$446 \$364 and \$364. The registration for 1936-1937 was 238 graduates, 53. The next session begins Sept 28 1937 and ends June 15 1938. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE 4200 East Ninth Avenue—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants, a total of 187. The course covers four years of nine months each. The entrance requirements are three years of collegiate work. The fees for residents of Colorado for each of the four years are respectively \$248 \$243 \$228 and \$228. Nonresidents are charged \$165 additional each year. The registration for 1936-1937 was 207 graduates, 48. The next session begins Sept 27 1937 and ends June 13 1938. The Dean is Maurice H. Rees, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE 333 Cedar Street—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1817. Instruction began in 1813. First class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884 the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887 Yale College became Yale University. Coeducational since 1916. The faculty consists of 137 professors and 213 lecturers and assistants, a total of 350. The requirements for admission are three years of collegiate work. The course covers four years of nine months each. The fees for the four years respectively are \$505 \$500 \$500 and \$520. The registration for 1936-1937 was 188 graduates, 47. The next session begins Sept 27 1937 and ends June 15 1938. The Dean is Stanhope Bayne Jones, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE 3900 Reservoir Road NW—Organized in 1851. First class graduated in 1852. The faculty is composed of 57 professors, 43 associate professors, 19 assistant professors and 118 instructors, total 237. Required for admission three years of collegiate work. The course of study covers four terms of eight and one-half months each. The present fees for each of the four sessions respectively are \$500 \$460 \$410 and \$450. The registration for 1936-1937 was 407 graduates, 117. The next session begins Sept 20 1937 and ends June 13 1938. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE 1335 H Street NW—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except 1834 to 1838 and 1861 to 1863 inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904 by an Act of Congress the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 55 professors and 117 instructors, demonstrators and a student, a total of 172. Two years of collegiate work is required for admission. The course covers four years of thirty-two weeks each. The fees for the four years respectively are \$550 \$550 \$500 and \$500. The registration for 1936-1937 was 253 graduates, 59. The next session begins Sept 22 1937 and ends June 8 1938. The Dean is Earl D. McKinley, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE Fifth and W Streets NW—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 33 professors and 81 lecturers and assistants, 114 in all. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. The fees for each of the four sessions respectively are \$269 \$269 \$259 and \$266. Registration for 1936-1937 was 135 graduates, 35. The next session begins Sept 27 1937 and ends June 10 1938. The Dean is Numa P. G. Adams, M.D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE 50 Armstrong Street and Druid Hills—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861 when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874.

It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131. The fees for each year are respectively \$212, \$192, \$165 and \$110. An additional fee of \$200 each year is charged nonresidents. The registration for 1936-1937 was 300 graduates. 48. The next session begins Sept. 22, 1937 and ends June 20, 1938. The Dean is William S. Middleton, M.D.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE 561 North Fifteenth Street—Organized in December 1912 by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. It has a faculty of 153. Two years of collegiate work is required for admission. The curriculum covers four years of eight and a half months each and one year's internship in an approved hospital. The fees for the first year are \$412 for each of the three following years \$400. The registration for 1936-1937 was 311 graduates. 64. The next session begins Sept. 24, 1937 and ends June 15, 1938. The Dean is Eben J. Carey, M.D.

CANADA

Alberta

UNIVERSITY OF ALBERTA FACULTY OF MEDICINE Edmonton—Organized in 1913. Coeducational since organization. Has given the complete six-year medical course since 1924. The faculty includes 8 full time and 77 part time professors, instructors, assistants and others, a total of 85. Tuition for the first year is \$150 for the second, third and fourth years \$215 for the fifth and sixth years \$225. The registration for 1936-1937 was 205 graduates. 32. The next session begins Sept. 24, 1937 and ends April 30, 1938. The Dean is Allen C. Rankin, M.D.

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE Bannatyne Avenue Winnipeg—Organized in 1883 as Manitoba Medical College. First class graduated in 1886 and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 26 professors and 75 instructors and assistants, a total of 101. Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university. The course extends over four years of eight months each and a hospital internship. The total fees for the five years respectively are \$266, \$266, \$266, \$266 and \$115. The registration for 1936-1937 was 214 graduates. 52. The next session begins Sept. 17, 1937 and ends May 18, 1938. The Dean is A. T. Mather, M.D.

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE Halifax—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty separate from the Halifax Medical College in 1885. In 1911 in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. It has a faculty of 24 professors and 43 demonstrators, lecturers and others, a total of 67. Requires for matriculation two years of arts. The medical course covers four years and a hospital internship of one year. The fees are \$317, \$317, \$307 and \$307 for each year respectively. \$250 additional registration fee payable by students outside the British Empire. The registration for 1936-1937 was 178 graduates. 28. The next session begins Sept. 14, 1937 and ends May 17, 1938. The Dean is H. G. Grant, M.D.

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE Kingston—Organized 1854. First class graduated in 1855 and a class graduated each subsequent year. The faculty numbers 56. The fee for the first year is \$208 and \$230 for each of the other five years. The course covers six years of thirty teaching weeks each. The registration for 1936-1937 was 294 graduates. 47. The next session begins Sept. 30, 1937 and ends May 25, 1938. The Dean is Frederick Etherington, M.D.

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL Ottawa, Avenue London—Organized in 1881 as the Western University Faculty of Medicine. First class graduated in 1883 and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 88. The course of study covers six years of eight months each. The total fees to residents of Canada for the last four years respectively are \$225, \$225, \$233 and \$258. The registration for 1936-1937 was 226 graduates. 46. The next session begins Sept. 20, 1937 and ends May 14, 1938. The Dean is F. J. H. Campbell, M.D.

UNIVERSITY OF TORONTO FACULTY OF MEDICINE Toronto—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The course of study covers six years of eight months each. The B.Sc. (Med.) degree is conferred at the end of the third or sixth year. It has a faculty of 67 professors and 285 lecturers, associates and others, a total of 352. The fees are \$198 for the first year, for the second \$370, \$268 for the third year, \$293 for the fourth and fifth years and \$325 for the sixth year. The registration for 1936-1937 was 834 graduates. 109. The next session begins Sept. 28, 1937 and ends May 14, 1938. The Dean is W. E. Gallie, M.D.

Quebec

MCGILL UNIVERSITY FACULTY OF MEDICINE 3640 University Street Montreal—Founded in 1823 as Montreal Medical Institution became the Medical Faculty of McGill University in 1829. First class graduated under the university auspices in 1833. No session between 1836-1839 owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop College. Coeducational since 1919. Three years of collegiate work is required for admission. The length of the medical course is five years, beginning with the session of 1936-1937 it was changed to four years followed by one year of internship. The faculty consists of 55 professors and 161 lecturers and others, a total of 216. The total fees for each of the five medical years are \$393. The registration for 1936-1937 was 483 graduates. 103. The next session begins Sept. 1, 1937 and ends May 31, 1938. The Dean is A. Grant Fleming, M.D.

UNIVERSITY OF MONTREAL FACULTY OF MEDICINE 1265 St. Denis Street Montreal—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891 by act of Parliament the Medical Faculty of Laval University (organized in 1878) was absorbed. Present name by act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The faculty numbers 195. One year of premedical college work is required for admission to a five year medical course. The total fees for each of the five years respectively are \$253, \$229, \$275, \$243 and \$218. The registration for 1936-1937 was 181 graduates. 51. The next session begins Sept. 15, 1937 and ends June 15, 1938. The Dean is Telesphore Parizeau, M.D.

LAVAL UNIVERSITY FACULTY OF MEDICINE Quebec—The Quebec School of Medicine organized in 1848 became in 1852 the Laval University Faculty of Medicine. First class graduated in 1855 and a class graduated each subsequent year. The faculty numbers 88. The fees for each of the medical years are \$175, \$185, \$175, \$175 and \$195 for residents of Canada. Nonresidents are charged an extra fee of \$190 each year. The premedical requirement is a B.A. degree. The registration for 1936-1937 was 271 graduates. 40. The next session begins Sept. 21, 1937 and ends May 31, 1938. The Dean is P. C. Dagneau, M.D.

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES Saskatoon—Organized in 1926. Coeducational. Offers the first two years of the medical course. Students require three more years of medicine for graduation. Two years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the second year. The medical faculty includes 7 professors and 3 lecturers and assistants, a total of 10. The fees are \$150 for each year. The registration for 1936-1937 was 50. The next session begins Sept. 23, 1937 and ends May 13, 1938. The Dean is W. S. Lind, M.B.

HOSPITALS APPROVED FOR TRAINING INTERNS

The following general hospitals containing 22,094 beds are considered in position to furnish acceptable internships for medical graduates

HOSPITALS, 712 INTERNSHIPS, 7,167

The terms used in the column Type of Internship are defined as follows

1 Rotating internships include services in medicine surgery pediatrics obstetrics and in the clinical and x-ray laboratories

2 Straight internships are limited to a single field

3 Mixed internships are those comprising more than one service but which do not include all of the six branches which constitute a rotating internship

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

For the benefit of graduates of approved medical colleges who desire an internship in Canada the Council on Medical Education and Hospitals of the American Medical Association has declared that hospitals which conform to the standards of the Department of Hospital Service of the Canadian Medical Association should be regarded as giving an internship equivalent in educational value to that offered by hospitals in the United States approved for intern training by the Council. It is understood however that this statement applies only to hospitals that are unqualifiedly approved under the Canadian plan and does not apply to that group referred to as Recommended.

The following list of hospitals revised to June 1937 has been furnished by the Department of Hospital Service

Name of Hospital	Location	Name of Hospital	Location	Name of Hospital	Location
Victoria General Hospital	Halifax N S	Ottawa Civic Hospital	Ottawa Ont	Hotel Dieu of St Joseph's Hosp	Windsor Ont

HOSPITALS APPROVED FOR RESIDENCIES IN SPECIALTIES

By the Council on Medical Education and Hospitals

The following hospitals, conforming to the standards of the Council, furnish acceptable residencies in the several specialties designated. Applicants are required to present evidence of graduation from an approved medical school and completion of at least one year of approved internship. In a few cases, equivalent experience in practice is accepted in lieu of preliminary hospital experience.

Regulations for Certification It is important to emphasize that residencies alone are not necessarily sufficient preparation for the practice of a specialty. Other types of training are also available and may be required. Candidates should acquaint themselves with the requirements by direct correspondence with the secretaries of the examining boards.

Statistical Data The statistical data have been obtained from annual reports covering the calendar year 1936. In a few instances earlier reports have been consulted. In most cases, this information is supplemented in the Council's files by inspection reports and by comments received from residents who have completed the listed service. The data should be examined with the following considerations in mind:

Chief of Service It is required that there be an organized and qualified staff in the department offering residencies. The names listed are those most recently reported as departmental chairmen. In university hospitals, professors usually are given. Blank spaces indicate recent unconfirmed changes or supervision is supplied by chiefs on parallel or rotating assignments. For credentials consult the American Medical Directory.

Inpatients The figures refer to total inpatients treated in the specialty. Exceptions are in anesthesia, radiology and pathology where total hospital admissions are used. In obstetrics, some hospitals include new-borns, others do not.

Per Cent Free An index to charity work performed although in every instance the majority of patients are available for instruction.

Outpatients Where available, the service is nearly always required.

Residencies Assistant Residents and Length of Appointment Information supplied indicates whether progressive services are available and over what period of time. The eldest in point of service is the resident and others assistant residents whether so designated by the hospital or not. Senior internships in specialties are classed as assistant residencies.

Salary It is advisable to confirm the quoted figure when applying. Unless otherwise indicated, compensation includes room and board. In fellowships, the hospital usually supplies maintenance only; the stipend is provided from other sources.

Deaths and Autopsies These are reported for the specialties. In anesthesia, pathology and radiology, figures are given for the entire hospital. Some obstetrical services include new-born deaths and autopsies.

Important All hospitals approved for residencies submit names of residents to the office of the Council for permanent credit and registration. It is in the interest of every house officer to assure himself that his name is properly recorded and that the correct dates of all appointments are submitted.

- a Compensation arranged by medical school and hospital
b Autopsy facilities for 12 months only
c In lieu of maintenance
d Twenty nine month appointments begin at no salary
e Hospital facilities by affiliation
f Fellowships available
g Appointments are from 7 to 60 months including 12 to 18 months internship Salary paid in lieu of maintenance
h General experience available in hospitals requiring previous approval internship same credit is given as to senior interns and general residents in hospital approved for internship
i Includes proctology
j One medical and one surgical appointment
k Dental as well as medical degree required
l Recruit appointments available in medicine and surgery
m Includes all specialties
n Include neuro surgery

- 10 Not a hospital outpatient and home delivery service
11 Training includes two years of service at City of Detroit Receiving Hospital in gynecology and two years at Herman Kiefer Hospital in obstetrics
12 Orthopedic resident covers eye ear nose and throat service
13 Apply to chief of service for information about affiliating hospital
14 Three assistant residents serve six months in all specialties
15 Separate appointments in roentgenology and in radiation therapy
16 Training in radiation therapy only
17 Several services include all specialties gynecology
18 Private and semi-private pavilions
19 Admissions are confined to children
20 No applications received
21 Affiliating usually with N Y Post Graduate Medical School New York City
22 Includes dermatology

APPROVED SCHOOLS FOR PHYSICAL THERAPY TECHNICIANS

The cooperation of the Council on Physical Therapy, the American Congress of Physical Therapy and the American Physiotherapy Association was secured in determining minimum educational requirements for physical therapy technicians. "Essentials of an Acceptable School for Physical Therapy Technicians" were adopted by the Council on Medical Education and Hospitals and passed by the House of Delegates of the American Medical Association at the Kansas City

meeting, May 9, 1936, as a result of the resolution introduced by Dr C B Reed of Illinois. The first list of approved schools appeared in THE JOURNAL, Aug 29, 1936, and the schools listed here represent the first revision.

Schools for Physical Therapy Technicians Conforming to the Standard Adopted by the American Medical Association in 1936

Name and Location of School	Director	Entrance Requirement	Length of Course	Student Capacity	Tuition	Certificate
Childrens Hospital Los Angeles ¹	John C Wilson M D	(a) R N (b) Grad phys ed	12 mos	10	\$125	Diploma
Stanford University Hospitals San Francisco	W H Northway M D	(a) R N (b) Grad phys ed	12 mos		\$175-\$250	Certificate
Walter Reed General Hospital Washington D C ²	Major W W McCaw M D	Grad phys ed	12 mos	10	None	Certificate

meeting, May 9, 1936, as a result of the resolution introduced by Dr C B Reed of Illinois. The first list of approved schools appeared in THE JOURNAL, Aug 29, 1936, and the schools listed here represent the first revision.

As for other types of medical assistants, there exist many commercial schools for physical therapy technicians throughout the country. Although they are self-

curriculum. Students turned out by commercial schools find their field of employment limited to massage establishments, clubs, gymnasiums, and so on, positions as assistants in hospital physical therapy departments or with members of the medical profession are virtually closed to them.

It has become increasingly apparent that many trained as "physical therapy technicians" in commercial schools

infringe on medical practice and too often are not prosecuted. Those trained in acceptable schools become thoroughly imbued with the necessity of working under the supervision of a qualified physician at all times and thus they become bona fide medical technicians.

The Council's essentials have been prepared with the purpose of designating acceptable basic courses covering all the more important phases of physical therapy. The essentials were printed in *THE JOURNAL*, Aug. 29, 1936, and may be secured through the office of the Council.

APPROVED SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

The accompanying list of schools for clinical laboratory technicians represents the first revision made since the House of Delegates of the American Medical Association adopted standards for such schools in 1936.

Since 1928 the American Society of Clinical Pathologists has concerned itself with the promotion of standards for clinical laboratory technicians through its Board of Registry. Because of the need for inspection of these schools in order to secure more complete and accurate data as to the organization, faculty, clinical facilities, and so on, the Board requested the cooperation of the Council in this work. As a result of the adoption of "Essentials of an Acceptable School for Clinical Laboratory Technicians" by the Association, the first list of approved schools was published in *THE JOURNAL*, Aug. 29, 1936.

Up to the present time 210 schools have been inspected by the Council's staff. The great majority of these courses are conducted in the departments of clinical pathology of the larger hospitals. Small groups of students, varying from two to six, are the rule. An increasing number of colleges and universities are offering this type of training. Basic sciences and the regular academic requirements occupy the first three years, the fourth year is given over to instruction and practice training in hospital laboratories affiliated with the educational institution. This training, as a rule, leads to a degree of Bachelor of Science in Medical Technology.

Whether the hospital laboratory training follows one or more years of regular college work, it should represent training where the theoretical and practical knowledge are combined. Here the student must be shown, not merely told, how things are done. The practical training should not be a by-product of the hospital laboratory service as has frequently been the method in the past, but it should take its place along with the other important educational functions of the hospital. Since the nature of the training during this year is essentially that of an apprenticeship, it should assume the relationship existing between instructor and pupil. Training in clinical laboratory technique must, of necessity, to have practical value, be coordinated and carefully directed to assure the student of a working knowledge of the fundamental principles and procedures. We should therefore strive to prevent the present tendencies toward uncontrolled education of laboratory workers in short courses offered by advertising schools.

Commercial schools, while they are comparatively few in number, persist in turning out large numbers of technicians in short courses. For the most part these schools are primarily interested in money-making and naturally do not adhere to high standards of admission

and training. While it is conceivable that a short course of training might fit a young woman to do the simple routine laboratory examinations, such courses will not prepare the technician to occupy a responsible position in a hospital laboratory, private laboratory, clinic or research department, where she would be called on to perform a wide variety of examinations in the various phases of clinical pathology. Training in commercial courses will not permit students to enter the examinations of the Board of Registry of the American Society of Clinical Pathologists. Those entering commercial school courses should realize fully that they cannot be certified according to the accepted standards and that the possibilities of securing desirable employment are not great.

The Council's essentials have been drawn up for the purpose of designating acceptable courses of basic training covering all the more important phases of clinical laboratory work. Courses offered in certain phases of the work, such as bacteriology or histology, have therefore not been listed under this scheme. A number of hospital laboratory departments provide such concentrated training, which in itself may be considered high grade, however, the Council is of the opinion that the broad basic training should precede such specialized experience.

Many hospitals now require their clinical laboratory technicians to be registered or eligible for registration. In its approval of hospitals, the Council has not insisted that only registered technicians be employed. It does, however, require that the laboratory department have a competent, well qualified staff. Registration is one of the important methods of identifying those who are qualified.

The Board of Registry has cooperated closely with the Council on Medical Education and Hospitals in the interchange of information and opinions concerning schools under consideration for approval. The Council is organized to maintain continuous contact with the approved schools through its annual survey of hospitals and system of periodic inspections, and an annual check of all the approved schools is made before revisions of the list are printed.

The following list contains the names of 125 schools for clinical laboratory technicians which have been carefully investigated and found to conform to the minimum requirements adopted by the House of Delegates at Kansas City, May 11-15, 1936.

"Essentials of an Acceptable School for Clinical Laboratory Technicians" are printed in *THE JOURNAL*, Aug. 29, 1936, page 682, and copies may be secured through the office of the Council. Additional schools will be approved as they make application and are found to conform.

MEDICAL STATISTICS

If the numerous medical statistical papers now being written are to fulfil their purpose, an understanding of the advantages and limitations of the statistical method when applied to medicine is essential. Statistical surveys can have no value unless the underlying diagnosis which serves as a starting point is reasonably correct and so well established that other persons of equal qualifications could make similar observations on the same patients. This important prerequisite cannot be ignored.

The quality of the actual manipulation of medical statistics also needs close attention. With this purpose in mind the *Lancet* published a series of articles on medical statistics by A. Bradford Hill,¹ and these have been collected and issued in book form. The statistical method, Hill states, is required in the interpretation of figures that are dependent on numerous influences. Its object is to determine whether individual influences can be isolated and their effects measured. Before this can be done, the selection of patients must be properly made. Thus, in experiments involving the treatment of patients who are to be compared with controls not given the specific treatment, any deliberate choice of individuals to be treated may lead to error. The treated group may differ from the untreated group in some characteristic which, known or unknown, has an influence on the results. This possibility may be illustrated by a hypothetical study of the treatment of colds by vaccine. If the vaccine is offered to volunteers, the vaccine treated group may be selected on the basis of greater frequency of colds and the expectancy of some advantage from the treatment. In any case volunteers cannot be considered comparable to a random sample of the population from which they are drawn.

Inquiries carried out by means of questionnaires, Hill points out, are *par excellence* those in which selection must be suspected. Since replies are received from

only a proportion of the individuals to whom the form is sent, those who choose to reply cannot be considered a representative sample of all individuals approached. The reasons for failure to answer are too manifold and usually too intimately connected with the purpose of the query to require comment.

In the diagram and graph, Hill states care should be used in selecting scales that give a clear picture of the meaning. A distorted mental image of the significance can be easily produced by improper planning of graphs or diagrams. When the "mean" of many observations is plotted, it is necessary to indicate also how much individual "scatter" is present. The calculation of the standard deviation is another integral part of satisfactory statistical expression. The symmetry of distribution of the individual observations around the mean and the calculation of the standard deviation for each set of observations, although involving some mathematics, cannot be neglected by the physician with data important enough to study in this manner.

It must be recognized, Hill emphasizes, that the observations used in statistical studies are merely samples of all the possible observations that might have been made. Hence the statistical technique in the handling of samples in relation to the universe becomes of great importance. The accuracy of a conclusion based on a sample depends on the size of the sample and the variability of the characters within the universe from which it is taken.

The chapters in Hill's book on common fallacies and difficulties should make invaluable reading for those who wish to avoid the worst pitfalls inherent in the statistical method. No comparison is valid, he states, "which does not allow for the sex differentiation of the fatality rates." Satisfactory standards of comparison must be employed, and their absence invalidates any comparative conclusions. The correct interpretation of either direct or indirect association between factors is also necessary and must be differentiated from purely fortuitous parallelism. Other important dangers are the failure to recognize changes in proportion rates, the use of crude death rates and the neglect, especially in problems of inheritance, to consider adequately chance expectancy. It must be recognized that in dealing with statistical papers it is "probabilities" that are weighed and never, as is sometimes suggested, any question of "mathematical proof." The crux of the matter is the tendency of workers to accept figures at their face value without considering all the factors responsible for them. Furthermore the science of statistics is also advancing and no more absolute agreement on method exists in that field than in clinical medicine. There is little doubt, however, that the quality of study of medical problems can be improved by greater attention to the fundamentals of the statistical method. All attempts to forward this purpose are highly desirable.

¹ Principles of Medical Statistics. By A. Bradford Hill. D.Sc. Ph.D. Cloth. Price 6s. Pp. 171. London: The Lancet Limited, 1937.

CEVITAMIC ACID STIMULATION OF SPECIFIC ANTIBODY PRODUCTION

Clinical and statistical observations have led to the belief that sufficiently prolonged vitamin deficiency causes a reduction in the normal antimicrobial defense of the human body. From this it is concluded that administration of vitamins or vitamin-rich foods will lead to a restoration of normal antibacterial resistance in deficiency diseases and might even increase natural resistance in normal persons on nondeficiency diets. The present commercial exploitation of yeast and numerous other vitamin-containing foods, is based largely on the latter assumption. Adequate experimental evidence in support of advertised claims, however, is still lacking.

In order to prepare animals for a test of the currently alleged immunizing power of vitamins, Juszat¹ of the hygienic institute at the University of Marburg, Germany, fed growing rabbits on routine laboratory diets rendered vitamin free by prolonged pressure cooking at 120 C. Rabbits thus fed were arrested in their normal development and often remained at a constant stunted weight for several months. Juszat found a reduction in the normal bactericidal titer in the blood serum of these stunted rabbits and a 90 per cent reduction in their power to form specific antibodies (e. g., horse precipitins) on the injection of antigens (e. g., horse proteins).

The therapeutic effects of numerous commercial vitamins were tested on these stunted animals. Juszat found, for example, that the addition of a commercial fat-soluble vitamin A to the routine deficiency diet (or its introduction by means of the stomach tube) was without demonstrable effect on the subnormal bactericidal titer of his deficiency animals. Furthermore, vitamin A feeding (or intragastric administration) did not improve the subnormal powers of the animals to produce specific precipitins.

Similar tests with commercial vitamin D gave equally discouraging results. Daily feedings (or intragastric injections) of small doses of viosterol led in about half of the deficiency cases to a transient partial restoration of normal bactericidal titer. This partial restoration lasted about a week and was followed in all cases by a rapid sinking of the antimicrobial index to a new low level. This presumably permanent fall in bactericidal titer was attributed by him to a beginning D hypervitaminosis. Furthermore, viosterol therapy did not improve the subnormal powers of his stunted animals to produce specific antihorse precipitins but almost invariably further depressed this immunizing function.

Equally discouraging results were obtained in tests with water soluble vitamin B complex. As this complex Juszat used a commercial preparation of dry yeast. Confirming Holsen's² previous experimental data, Juszat found that the addition of dry yeast to routine

nondeficiency laboratory diets had no demonstrable effect on the bactericidal index of normal rabbits. In his stunted rabbits he found that from 5 to 8 Gm. of dry yeast added to the daily deficiency diet led to no demonstrable improvement in blood titer. Nor would yeast fed stunted rabbits produce antibodies of higher titers than his non-yeast fed stunted controls.

Disappointing results were also obtained in therapeutic tests with water soluble vitamin C. As vitamin C he used both native and commercially available synthetic cevitic acid, both being tested in the form of sodium salts. Juszat found that the addition of from 50 to 100 mg. of cevitic acid to his daily deficiency diet gave no demonstrable improvement in the serologic titers of the stunted animals nor would such therapy improve subnormal antibody production of stunted rabbits.

Results of theoretical interest, however, were obtained on intravenous injection of massive doses of cevitic acid, from 33 to 66 mg., for example, injected intravenously caused a transient rise in the normal (or subnormal) bactericidal index. The height of this cevitic acid immunity was reached in about four hours. The heightened serologic titer was usually lost well before the end of twenty-four hours. By increasing the intravenous dose of cevitic acid to from 200 to 500 mg., a trebling of bactericidal titer could be demonstrated as late as the twenty-fourth hour, with subsequent fall to the initial titer well before the sixth day. Dr. Juszat's most important contribution, however, is his demonstration of the stimulating effect of intravenously injected cevitic acid on specific antibody production. Immediately before each immunizing dose of horse protein, for example, his normal (or deficiency) rabbits were given massive intravenous doses of cevitic acid, control animals being injected with the same horse protein but without previous cevitic therapy. Ten days after his last antigenic dose his cevitic acid reinforced normal rabbits yielded a serum with a precipitin titer of approximately 1:100,000, the average control titer being 1:10,000.

Dr. Juszat afterward simplified this technique by adding 100 mg. of cevitic acid to each immunizing dose of horse protein. An average five to seven fold augmentation in specific precipitin production was noted in the stunted rabbits by this simplified technique. In his control deficiency rabbits, for example, the average precipitin titer rarely exceeded 1:1,000. Titers of 1:10,000 and even as high as 1:100,000 were occasionally reached by immunization of stunted rabbits with the horse protein-cevitic acid complex, injected intravenously.

Although Juszat's data do not confirm the currently advertised immunizing power of orally administered commercial vitamins, his discovery that massive doses of cevitic acid injected intravenously demonstrably increase specific antibody synthesis is a discovery of clinical promise and basic scientific interest. If confirmed, his observations suggest numerous practical

² Holsen, Zisch. *f. Vitaminforsch.* 1: 3, 1932.

applications to specific diagnosis, vaccine therapy and treatment of chronic bacterial infections. In this connection Hochwald³ has recently reported that in his hands cevitamic acid seemed to play an equally important accessory part in allergic and anaphylactic phenomena.

Current Comment

MEDICAL SCHOOL SURVEY

The Council on Medical Education and Hospitals has now completed the survey of medical schools that was begun three years ago. The procedure employed in making the study has been described by Dr. Herman G. Weiskotten,¹ and some of the more significant observations were reported to the House of Delegates at Atlantic City.² Confidential reports in graphic form have been sent to all the schools for the purpose of assisting them in strengthening their respective programs. In response to this stimulus there are already indications of considerable activity, and substantial improvements are being made in standards of admission, in numbers and qualifications of faculty personnel, and in the kind and amount of practical experience comprised in the clinical teaching. While much still remains to be done, the great majority of schools give evidence of healthy growth and development.

INTERNSHIPS AND RESIDENCIES

Half a century ago newly fledged physicians served for a number of years as apprentices or assistants to older men, thus securing actual experience in the practice of medicine before assuming the responsibilities. The development of aseptic surgery, the ever growing importance of indirect methods of examination and the rapid increase in the number of hospitals have led to the development of an institutional apprenticeship or internship which is considered far more desirable than the old assistantship. So important has the internship become that thirteen schools in the United States have made it a requirement for their medical degree, in eighteen states it is legally prerequisite to licensure. Of the graduates of 1936, excluding those schools in which internship is obligatory, 91.8 per cent voluntarily chose to continue their education in this manner. Fifty-four schools have not made internship compulsory, this does not mean that they underestimate its value. The university which is unable to provide internships under the supervision of its own faculty for all its graduates cannot base its degree on an extramural experience which it cannot guarantee or closely supervise. The internship is now generally recognized as a necessary stage in the training of the physician and is a prerequisite for the position of resident in one of the medical specialties. It is almost universally required for membership in those scientific societies which represent the clinical branches

of medicine. Following the internship comes the residency, in general devoted to a limited field. This period of training extends often from two to five years. It represents an important part of the accepted preparation for the practice of a specialty. The examining boards of medicine, surgery, pediatrics, and so on, require a specified amount of institutional apprenticeship of this character. Usually it is necessary to supplement the residency by systematic courses in related medical sciences, such as are increasingly available at the larger universities. The list of approved residencies, pages 693 to 707, has been considerably amplified, so as to give to those interested, as completely as possible, the pertinent data regarding the services described.

GOVERNMENT TO REGULATE THE NAMING OF COMPOUNDS

According to a report in *Drug Trade News*, the Food and Drug Administration has decided to start active enforcement of its long-standing but well-nigh dormant regulation holding a drug product to be misbranded if it contains more than one active medicinal agent but is named after only one of its constituents. The Council on Pharmacy and Chemistry has always objected to the hiding of other active ingredients under a single name. To call a product "X-compound," the latter word to serve as a mask to hide potent drugs which, in some instances, actually are more powerful than the drug from which the "compound" takes its name, is deceptive, whether intentional or not. Organized medicine has insisted that a product should be truthful in name as well as fully named. The stand taken by the Food and Drug Administration that all products should be made to declare clearly and accurately any active ingredients other than the one indicated by the title is a definite advance in the protection of the public against hidden drugs in proprietary medicinal products.

BASAL METABOLISM IN CHILDREN

A special feature of the January issue of the *American Journal of Diseases of Children* was a supplement devoted to two articles dealing with the basal metabolism of children. Talbot and his collaborators¹ recorded the metabolism of 106 healthy girls attending a private school in Boston. The observations were subjected to severe tests for normality and basality and when all the desired information was recorded it was used in group studies. As a result of the careful analysis of the measurements obtained, several important points were established. The most significant factor modifying the metabolism, the authors believe, is geographic location, which cannot be separated from climate. Race does not appear to affect the metabolism, but there is a definite relation between body weight and heat production. Mathematically, the correlation of heat production was closer with body weight than with any other factor studied. A correlation also appeared to exist between the creatinine output and the basal heat production. Since the creatinine output is accepted as a measure of

active protoplasmic tissue, it may be said with assurance that the active protoplasmic tissue of the body is the principal factor of importance connected with heat production. The main difference between the adult and the child, according to Lewis and his collaborators,² is that the former is a finished product which remains in statu quo, and the latter is continuously changing. This fact should be considered each time a metabolism reading is interpreted by the clinician. The purpose of the investigations made by Lewis's group was to maintain a study of 100 normal children more or less evenly divided between girls and boys on whom observations were begun not later than one month after birth. Their report is based on studies begun in 1932 as part of the general program of the Child Research Council. The results, therefore, are based on a longitudinal study of normal children. There were 366 basal metabolism tests on fifty-two boys and 271 basal metabolism tests on forty-one girls, all between the ages of 2 and 12 years. The treatment of the data thus gathered indicates that, for the group of normal children under investigation, three of the methods of expressing heat production, namely, calories per hour referred to weight and to surface area, respectively, and calories per hour per square meter referred to age, give the lowest degrees of dispersion. The precise relationship of body build to the basal metabolism of the child, however, cannot be determined until more complete statistical studies in close correlation with anthropometric and other physiologic measurements are available.

EYEWASH FROM THE GENERAL

On August 6, 1937, an announcement from the National Broadcasting Company indicated that General Hugh S. Johnson, rough rider of the Blue Eagle, will make his debut as a radio commentator over the Blue Network on September 27, 1937, being sponsored by the Grove Laboratories, makers of "Bromo Quinine." Quite recently the Federal Trade Commission issued a complaint against the Grove Laboratories, Inc., alleging misleading and exaggerated advertising in the sale of "Grove's Laxative Bromo Quinine Tablets." Moreover, the laboratories stipulated with the commission "to discontinue certain misleading advertising representations in the sale of 'Grove's Emulsified Nose Drops.'" In May 1935 the Food and Drug Administration published a notice of judgment alleging that Grove's Emulsified Nose Drops were sold under fraudulent therapeutic claims. Whether or not these little incidents will embarrass the General's future in radio is, of course, a matter for thought. Once upon a time notables did not hesitate to associate their names with the claims of nostrums and "patent medicines"—for "Peruna" Admiral Schley, Rear Admiral Hichborn and Julia Marlowe testified, the divine Sarah Bernhardt exploited "Duffy's Malt Whiskey," and Madam Schumann-Heink told of the wonders of "Fahrney's Blood Vitalizer." The exact place that General Hugh S. Johnson will occupy in this hall of "fame" will no doubt become apparent.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Graduate Courses—Stanford University School of Medicine, San Francisco, will conduct graduate courses in cooperation with the city department of health and the San Francisco Hospital, September 6-10. The subjects will include x-ray diagnosis and therapy, emergency surgery and fractures, diseases of the genito-urinary tract, cardiology and electrocardiography, diagnosis and treatment of malignant tumors, surgical anatomy. There will be ward rounds in medicine and clinics in the medical specialties. Two general meetings Monday and Wednesday evenings will be addressed respectively by Drs. Maurice L. Tainter on "Evaluation of Recently Introduced Drugs" and William P. Shepard, "Problems in Industrial Health."

COLORADO

Study of Health Agencies—A study of public and private health agencies of Colorado Springs and El Paso County is under way by Ira V. Hiscock, C. P. H., professor of public health, Yale University School of Medicine, New Haven, newspapers report. He was invited to make the survey by the Community Chest with a view to recommending a more adequate health service.

Tularemia Following Tick Bite—A specimen of blood received from Dr. Charles E. Fitzgerald, Craig, was identified by the state department of health recently as showing positive reaction to tularemia. The disease developed from a tick bite of the finger. The patient denied handling dead animals and the point of inoculation was typical in appearance of an infected insect bite which went on to a small ulcer formation. Dr. Fitzgerald had two similar cases last spring, *Colorado Medicine* reported. So far as the laboratory is aware, these cases of tularemia due to tick transmission are the first to be reported in Colorado.

CONNECTICUT

State Medical Journal to Become Monthly—At the annual meeting of the Connecticut State Medical Society in May it was voted to make the society's journal a monthly publication beginning with January 1938. The journal has been issued quarterly since it was launched in August 1936. The secretary on scientific work, Dr. Stanley B. Weld, Hartford, will continue as editor.

Dr. Cushing Named Director of Studies in History of Medicine—Dr. Harvey Cushing, Sterling professor of neurology emeritus, Yale University School of Medicine, has been appointed director of studies in the history of medicine with rank of professor at the medical school. Dr. Cushing recently reached the age permitting him to retire. He is also Moseley professor of surgery emeritus of Harvard University Medical School, Boston.

DISTRICT OF COLUMBIA

Medical Bill in Congress—H. R. 8298, introduced by Representative Dingell, Michigan, proposes to provide for the issuance of a license to practice naturopathy in the District of Columbia to Patrick Joseph Clifford.

FLORIDA

Personal—Stewart G. Thompson, Dr. P. H., Jacksonville, managing director of the Florida Medical Association, has resigned as secretary-treasurer of the Florida Public Health Association, and as director of the bureau of vital statistics of the state board of health to devote full time to his work with the state medical association.

Society News—Dr. Chadbourne A. Andrews, Tampa, was elected president and Dr. Lauren M. Sompayrac, Jacksonville, secretary of the Florida Society of Dermatology and Syphilology at its annual meeting in Jacksonville, June 6.—Dr. Arthur L. Walters, Miami Beach, and A. Daniel Ameri, Coral Gables, addressed the Dade County Medical Society, Miami, June 4, on "Modern Management of Diabetes Mellitus" and "Recent Advances of Present-Day Treatment of Syphilis."

Bites' respectively—Dr James R Boulware Jr Lakeland addressed the DeSoto-Hardee-Highlands County Medical Society in Wauchula June 8 on "Pediatric Practice in South Florida—A Comparative Study"

IDAHO

Hospital News—A new hospital was opened at Emmett, June 14 twelve private rooms and two wards are available for the care of patients. Full modern equipment including air conditioning has been installed throughout, according to *Northwest Medicine*

ILLINOIS

Dr Jirka Resigns as Health Commissioner—The resignation of Dr Frank J Jirka as health commissioner of Illinois, effective September 1, was announced in the newspapers August 8. His successor has not been appointed. Dr Jirka has held the position since 1933. He graduated from Northwestern University Medical School in 1910 and is assistant professor of surgery at the University of Illinois College of Medicine Chicago.

Courses in Obstetrics and Pediatrics—The state department of public health, through the University of Illinois College of Medicine, Chicago, and in cooperation with the educational committee of the Illinois State Medical Society, is offering courses in obstetrics and pediatrics for registered physicians of the state. A registration fee of \$10 should accompany the application to take the course and checks should be made payable to the university. Applications should be sent to Mr G R Moon, examiner and recorder of the Chicago Professional Schools, University of Illinois 1853 West Polk Street, Chicago.

Society News—Dr Samuel M Feinberg, Chicago, was the guest speaker before the Hancock County Medical Society in Hamilton, July 21, he discussed hay fever—The Macoupin County Medical Society was addressed, July 27, by Drs Winston H Tucker on "Premarital Health Examination", Paul H Harmon, "Polio-myelitis" and Lyman Stewart, "Is Prostatectomy to Be Replaced by Transurethral Resection?" All are from Springfield—Dr Edward Ross, Alton, addressed the Madison County Medical Society at the Alton State Hospital, August 6 on "Dementia Praecox and Its Relationship to General Practice"

Personal—Dr Benjamin Gruskin director of oncological research in the department of pathology Temple University School of Medicine Philadelphia will spend one week of each month at Paris Hospital Paris where he will direct a newly established department of cancer research it is reported—Dr Richard Clark Benkendorf Chicago has been appointed superintendent of the Elmgrove Sanatorium Bushnell succeeding Dr Arthur K Drake, resigned—Dr Winston H Tucker, coordinating epidemiologist state department of health, Springfield, has been appointed health officer of Evanston, succeeding Dr John W H Pollard resigned. The appointment is effective September 1. Dr Tucker was chosen by the Evanston branch of the Chicago Medical Society, Mayor Penfield having asked that group to recommend a candidate, it was reported.

Chicago

Graduate Courses at Northwestern University—Graduate courses in cardiorenal-vascular medicine and urology will be offered at Northwestern University Medical School during September. The course in medicine will begin August 30 and will continue until September 11, the one in urology will begin September 13 and continue through September 25. Registration is limited to twenty students in each division. The tuition fee is \$50 for each course and a deposit of \$10 is required to hold a place in the class.

IOWA

More Syphilis Cases Reported—A study has been completed of the 1547 cases of syphilis reported to the Iowa State Department of Health for the first six months of 1937. This is two and a half times as many as the 615 cases for the same period in 1936. Linn County has made the most marked improvement in notification with twelve times as many cases reported to July 1 as compared with the same period in 1936.

Personal—Edward A Benbrook DVM professor and head of veterinary pathology Iowa State College of Agriculture and Mechanic Arts Ames has resigned from the state board of basic science examiners. Frank M Smith professor of zoology Buena Vista College Storm Lake will fill the unexpired term. William Strunk DSc Decorah Iowa has succeeded Dr Benbrook as secretary of the board.

Appointments to State Department of Health—Dr James P Sharon Fort Dodge, has been appointed associate director in charge of venereal disease control division of preventable diseases, Iowa State Department of Health effective July 1. He recently completed six months' special training in venereal disease work at Johns Hopkins Hospital Baltimore. He graduated from St Louis University School of Medicine St Louis in 1923. At the same time Dr Charles K McCarthy became director of activities for the control and prevention of tuberculosis, to be carried on by the state medical society, Iowa Tuberculosis Association and the state department of health. Dr McCarthy graduated from Tufts College Medical School, Boston in 1930.

KANSAS

Personal—Dr John C Fear Waverly was guest of honor at a celebration at City Park July 1 marking his completion of sixty years in the practice of medicine. Dr Fear graduated from the College of Physicians and Surgeons Keokuk Iowa. He has been mayor of Waverly five times and has served one term in the state legislature—Dr Clyde W Miller Wichita has been appointed superintendent of the Sedgewick County Hospital Wichita succeeding Dr Harry O Anderson who returned to private practice—Dr Rosecoe T Nichols Hiawatha has been appointed a member of the state board of health to succeed Dr Charles W Robinson Atchison who resigned.

MASSACHUSETTS

Medical Center for Rural Physicians—A gift of \$300,000 to the Boston Dispensary has been pledged by William Bingham 2d to complete the building of the Joseph H Pratt Diagnostic Hospital and finance its operation according to recent announcements. The donation, supplementing a previous gift of \$400,000 made by Mr Bingham in April will be devoted to the creation of a medical center for the rural physicians of New England. The hospital is named in honor of Dr Pratt who is professor of clinical medicine at Tufts College Medical School Boston. It was reported that Mr Bingham is primarily interested in rural medicine and his desire is to provide a medical center at which the development of rural medicine may be planned and supervised. The report pointed out that under normal conditions a country doctor, because of his devotion to his practice and his geographic isolation, requires months or years to learn of each new development in the field of medical science. Everything will be done to make it possible for patients needing diagnosis, patients from any corner of New England and from any economic group to get the latest medical advice and for the country doctor to profit from the knowledge and experience of specialists. According to *Lancet* physicians will take turns studying at the Pratt Hospital. Mr Bingham will pay their expenses in Boston and arrange for exchange doctors' to substitute for them in their home towns. In addition, all New England physicians will have the opportunity to send the 10 per cent or so of their most puzzling cases" to the Pratt Hospital for study and diagnosis.

MICHIGAN

Cooperative Graduate Courses—The department of graduate medicine of the University of Michigan in conjunction with Wayne University College of Medicine and the Michigan State Medical Society will begin, September 13, a series of graduate courses in Battle Creek and Kalamazoo jointly. Bay City, Flint, Grand Rapids, Lansing and Jackson, jointly. Marquette and jointly in Traverse City, Cadillac, Manistee and Potosky. The lectures and demonstrations will cover the field of general medicine and will be held one day each week for eight weeks. Additional information may be obtained from the department of graduate medicine University Hospital Ann Arbor.

Medical Research Institute—The United Automobile Workers has set up in Detroit a Medical Research Institute under the direction of Dr Frederick C Lendrum according to a press release published in the *Detroit Medical News*. The institute was organized for research in industrial diseases, notably lead poisoning, silicosis, chloromum poisoning and industrial skin diseases. It occupies a suite of rooms in the Hoffmann Building with three examining rooms, laboratory, x-ray room, photo dark room and consulting room representing an investment of about \$10,000. Examinations of workers are to be made by a group of physicians who are members of the Wayne County Medical Society, it was said. Dr Emory R Hayhurst, Columbus for many years consultant in industrial hygiene for the Ohio State Board of Health directed the organization of the institute according to the announcement.

MINNESOTA

Mayo Home to Be Used for Educational Purposes—The residence of Dr. and Mrs. William J. Mayo, Rochester, and the east half of the block on which it stands will be deeded for the Mayo Foundation to a board of trustees to aid the educational aims of the foundation and the University of Minnesota, according to a recent announcement. The members of the board of trustees are, tentatively, Dr. Donald C. Balfour, chairman, Dr. Waltman Walters and Mr. H. J. Harwick. The residence, which was built in 1916, is of reinforced concrete faced with stone and is fireproof. The two lower stories and the tower contain living rooms; the third story is occupied by an assembly room. Dr. Mayo intends to endow the property sufficiently to prevent taxes and general maintenance from becoming a burden on the foundation, it was stated, and details of the use to which the property will be put will be formulated by the trustees. Dr. and Mrs. Mayo will build a smaller house on the southwest section of the block.

Southern Minnesota Meeting—The Southern Minnesota Medical Association held its annual meeting in Winona August 11. At the morning session at the Winona High School speakers included

Dr. Fred H. Albee, New York, The Importance of the Liver at the Top of the Femur as a Stabilizing Influence
Dr. Russell M. Wilder, Rochester, The Use of Protamine Insulin
Dr. Lewis I. Younger, Winona, Accurate Diagnosis of Appendicitis
Dr. Ernest M. Hammes, St. Paul, Acute Lymphocytic Meningitis

At the afternoon session, which was held on the steamboat *Capitol*, a group of case reports was presented by Drs. Moses Barron, Minneapolis, on "Pathogenesis and Treatment of Valvular Heart Disease"; Alexander E. Brown, Edwin G. Bannick and Harold C. Habein, Rochester, "The Use of Sulfanilamide (Prontylin)," and Frederick P. Moersch, Rochester, Review of the Hypoglycemic Treatment of Mental Disease. An evening session was held at the Winona Country Club with Drs. William J. Mayo, Rochester, Alfred W. Adson, Rochester, president of the Minnesota State Medical Association, and Harold C. Habein, Rochester, president of the Southern Minnesota association, as speakers.

MISSISSIPPI

Society News—The North Mississippi Medical Society was addressed at its quarterly meeting in Holly Springs, July 28, by Drs. Joseph F. Hamilton, on "Etiology, Pathology and Diagnosis of Infantile Paralysis"; Willis C. Campbell, "Orthopedic Treatment of Poliomyelitis"; and Hugh M. A. Smith Jr., "Emergency Treatment and Transportation of Fractures." All are from Memphis, Tenn.

Society Sponsors Graduate Course—The Central Medical Society is sponsoring the following program to be offered in Jackson, September 7, by members of the faculty of the University of Tennessee College of Medicine, Memphis:

Dr. William T. Pride, Care of an Obstetric Case
Dr. George R. Livermore, Urinary Lithiasis
Dr. Gilbert J. Levy, Acute Poliomyelitis with Special Reference to Its Early Diagnosis and Prevention
Dr. John L. McGehee, Acute Intestinal Obstruction
Dr. Willis C. Campbell, Fractures About the Ankle
Dr. Edward Clay Mitchell, The Care of the Normal Child from Birth Until School Age with Consideration of Those Factors Affecting Its Growth and Development
Dr. Philip M. Lewis, What the General Practitioner Should Know About the Eye
Dr. W. Likely Simpson, Foreign Bodies in Air and Food Passages

MISSOURI

Personal—Dr. Ralph A. Kinsella, St. Louis, has been appointed a member of the city plan commission.—Dr. Clifton Smith, staff physician at the State Hospital No. 2, St. Joseph, has been appointed superintendent of the St. Louis Training School, succeeding Dr. George A. Johns, resigned.

Committee on Syphilis Control—At a meeting of the council of the Missouri State Medical Association July 14, Dr. Dudley S. Conley, Columbia, president of the association, announced the appointment of a committee for the study of the control of syphilis with the following members: Drs. Garold V. Stryker, St. Louis, chairman; Charles C. Dennie, Kansas City; Walter S. Sewell, Springfield; Quitman U. Newell, St. Louis; and Caus T. Ryland, Lexington.

Society News—Dr. Fredrick W. Shaw, Richmond, Va., addressed the Phelps and Crawford County Medical Society in Rolla July 12 on "Pathogenic Fungi."—Dr. Andy Hall Jr., St. Louis, addressed the Randolph-Monroe County Medical Society, Moberly, June 8 on "Urologic Problems of the General Practitioner."—A program on syphilis was presented at a meeting of the South Central Counties Medical Society, Houston, June 18 by Drs. Garold V. Stryker, Robert E. Britt and John A. Brennan, all of St. Louis.

NEW YORK

County Society Names Executive Secretary—The Onondaga Medical Society recently voted to establish a central office with an executive secretary in charge and has appointed R. Marcus Dick, Cranston, R. I., to the position. Mr. Dick graduated from the college of business administration of Syracuse University in the class of 1937.

Pneumonia Control Program Expanded—Production of serums for pneumonia of types V, VII and VIII and any additional types that may be found to be of value in the future will be made possible by a fund of \$400,000 appropriated by the recent legislature to the state department of health. About \$150,000 will be used to enlarge the facilities of the division of laboratories to meet the increased load of serum production. In addition, the department will be able to develop further its typing facilities, to extend the program of graduate professional education through the Medical Society of the State of New York and of education for the general public and to do more extensive epidemiologic research when occasion offers. The pneumonia control program in its present form was begun Nov. 1, 1935, as a cooperative undertaking of the state health department, the state medical society, the State Association of Public Health Laboratories, the Metropolitan Life Insurance Company and the Commonwealth Fund, the last two giving financial assistance.

An Outbreak of Cowpox—Infection of a herd of cows with cowpox through contact with a recently vaccinated person and subsequent infection of other persons from the cows was reported in *Health News*, the bulletin of the state department of health, August 9. An 18-year-old boy who assisted in the care of a herd of about twenty cows was vaccinated June 7. His vaccination ran an uncomplicated course. About June 18 it was noticed that some of the cows had cowpox. Ten days later a younger brother of the first boy developed lesions on the forearm that were described by a physician as typical vaccination pustules. The second boy became acutely ill and later the pustules disappeared leaving typical vaccination scars. About July 5 another brother of the two developed a "vaccination lesion" on his hand, which ran an uncomplicated course. Other members of the family were not infected. The father was the only other one who handled the cows and he had been vaccinated four times. The mother had once been vaccinated but three other children who were not infected had never been vaccinated.

New York City

Paul Hoeber Dies—Paul B. Hoeber, medical book publisher, died August 20, in Lenox Hill Hospital, of perforated duodenal ulcer. Mr. Hoeber was for many years a book dealer specializing in medical books, developing his publishing activities simultaneously. In recent years he had devoted himself entirely to the publishing field under the imprint Paul B. Hoeber, Inc. In 1935 his firm was absorbed by Harper and Brothers and became the medical department of that house. Mr. Hoeber continued as president of the division, and its publications bore the imprints of both firms. In addition to books and monographs, Mr. Hoeber published *Annals of Medical History*. He was 53 years old.

Distribution of Pertussis Vaccine Discontinued—The New York City Department of Health recently announced that because of the equivocal results attending the use of pertussis vaccine and the difference of opinion concerning its prophylactic value, the vaccine will no longer be administered at baby health stations on request. Its administration will be limited to a controlled experimental project now being carried on under the direction of Dr. Ralph Muekenfuss, director of laboratories at the Williamsburgh-Greenpoint health center and at the Prospect Clinic in Brooklyn. Through this project the department hopes to arrive at definite conclusions as to the value of the vaccine for the prevention of whooping cough.

Examination for School Medical Supervisor—The New York City Board of Education announces an examination for license as school medical supervisor in the bureau for children with retarded mental development to be held during the week of October 11. The final date for acceptance of applications is September 1. Forms may be obtained at the office of the board, 500 Park Avenue, or will be sent on receipt of a request accompanied by a large, self-addressed stamped envelope. Applicants must have graduated from a class A medical school, must have a license to practice in New York, must have had twelve semester hours in certain approved courses in school and public health administration and must be between 30 and 45 years old. They must be citizens, except that an alien may be appointed if he has made application to become a citizen. The salary is \$4,000 a year. It is requested that all inquiries be made in writing.

Hospital Employees Enjoined from Striking—A temporary injunction restraining members of a hospital employees' union of Greater New York from calling a strike, picketing or interfering with the patients employees or visitors at the Jewish Hospital in Brooklyn was issued August 9 by Supreme Court Justice Albert Conway. The justice incorporated in his decision the hospital's complaint that recited the disorders at the hospital last March when the union took possession of the kitchen and laundry. He said "The affidavits establish that uninterrupted hospital service for the people of the city is so vital for the preservation of the general health of the community, and especially children the sick and infirm that any organized effort to interfere therewith must be regarded as an act of hostility to the common good and such an unlawful object as to demand the exercise of the equity power of the court to the fullest extent."

NORTH CAROLINA

Society Opposes Federal Control of Practice—The executive committee of the Medical Society of North Carolina at a meeting in Raleigh July 13 adopted a resolution expressing opposition to any plan that involves federal supervision and control of medical practice in the United States. The committee's action was taken following reports from the annual session of the American Medical Association indicating that a plan is being contemplated to place the practice of medicine in the United States, as it involves the care of indigent persons under federal government control, the resolution stated. The committee, representing the society, affirmed its willingness to cooperate at all times with the proper authorities in order to secure adequate medical care for the indigent, yet at the same time recorded its conviction that such care is a state and county responsibility and is properly a function of the local governmental unit and the local medical profession.

SOUTH CAROLINA

Annual Piedmont Assembly—The annual Piedmont Post Graduate Clinical Assembly will be held in Anderson September 8-10. Among the speakers announced on the preliminary program are the following:

Dr. Kenneth M. Lynch, Charleston, The Pathogenesis of Tuberculosis
Dr. David T. Smith, Durham, N. C., Diagnosis and Treatment of Chronic Pulmonary Infections Which Simulate Tuberculosis
Dr. Frank K. Boland, Atlanta, Treatment After Laparotomy
Dr. Marion C. Pruitt, Atlanta, Diagnosis and Treatment of Common Diseases of the Anorectum
Dr. Addison G. Brenner, Charlotte, N. C., Down the Gastro Intestinal Tract with Camera and Tools

At a banquet the evening of September 9 Dr. Boland will speak on Crawford Long and the Discovery of Ether Anesthesia.

TENNESSEE

Personal—Dr. Everett E. Carrier, Johnson City, assistant health officer of Washington County since 1934, has been appointed health officer to succeed Dr. Wallace J. Poole who resigned. Dr. Joseph L. Conyers, Gates, has been appointed assistant to Dr. Carrier.

Society News—Dr. John Shelton Horsley, Richmond, Va., addressed the Chattanooga and Hamilton County Medical Society, July 1, on "Early Diagnosis and Treatment of Cancer." Drs. Albert Weinstein and James Frazier Bunn, Nashville, addressed the Smith County Medical Society, Carthage, July 2, on diabetes and diarrheal diseases of children, respectively. Drs. Edward C. Mitchell and John J. Shea, Memphis, addressed the Gibson County Medical Society, Trenton, July 26 on "Summer Diarrhea" and "Upper Respiratory Infection as a Cause of Diarrhea in Children" respectively. Dr. James W. McElroy addressed the Memphis and Shelby County Medical Society, July 6 on "Congestive Heart Failure." Drs. William C. Colbert and William M. Adams, Memphis, addressed the Fayette-Hardeman Counties Medical Society recently on "Coronary Thrombosis and Angina Pectoris with Special Reference to Differential Diagnosis and Relationship of Plastic Surgery to General Practice" respectively.

WASHINGTON

Hospital News—St. Peter's Hospital, Olympia, celebrated the fiftieth anniversary of its founding recently. The present building was occupied in 1924. Ground was broken June 22 for a new orthopedic wing to the Swedish Hospital, Seattle. Gov. Clarence D. Martin turned the first spadeful of dirt.

Personal—Dr. Richard A. Koch, Tacoma, has been appointed health officer of Whitman County. Dr. Jesse H. Hendry, Tacoma, has been appointed physician in charge of Tacoma Hospital, a federal institution for Indians, to succeed Dr. John N. Allen.

Medical Murals at Fair—The Pierce County Medical Society, the Tacoma Public Health Council and the Tacoma District Dental Society are sponsoring a display of thirty murals at the Western Washington Fair to be held in Puyallup in the fall. According to *Northwest Medicine*, the murals depict the history of medicine from the earliest period to the present and include portraits of famous figures.

WEST VIRGINIA

Committee on Syphilis—Dr. William S. Fulton, Wheeling, president of the West Virginia State Medical Association, has appointed a committee on syphilis to cooperate with the state health department and other agencies in the current campaign. Dr. William M. Sheppe, Wheeling, is chairman of the committee and Drs. Ray M. Bobbitt, Huntington, and Amos H. Stevens, Fairmont, are the other members.

Personal—Dr. Turner E. Cato, New Cumberland, former health officer of Hancock County, has been appointed health officer of Kanawha County, with headquarters in Charleston. Dr. Charles N. Scott, Alloy, has been appointed head of the bureau of venereal diseases in the state department of health. Dr. Donald L. Butterfield, Moundsville, has been appointed medical adviser of the state department of public assistance. He will have charge of work with crippled children, adult physical rehabilitation and emergency medical and hospital care of the department's relief load.

HAWAII

Special Courses—Dr. Franklin G. Ebaugh, professor of psychiatry, University of Colorado School of Medicine, Denver, is conducting a course in mental hygiene at the University of Hawaii during the summer and is making a survey of mental hygiene problems in Honolulu under the auspices of the chamber of commerce. It is planned to establish a psychiatric clinic. Dr. Ernestine V. Kandel, Chicago, and Christopher J. Hamre, Ph.D., associate professor of zoology, University of Hawaii, recently gave a series of graduate lectures on hematology before the Honolulu County Medical Society.

GENERAL

Casselberry Prize to Be Awarded—The American Laryngological Association announces that the Casselberry Prize of \$500 is now available for a prize award, decoration or the expense for original investigation or research in laryngology and rhinology. Theses or reports of work must be in the hands of the secretary, Dr. James A. Babbitt, 1912 Spruce Street, Philadelphia, before February 1.

Society News—The second National Conference on Educational Broadcasting will be held in Chicago at the Drake Hotel, November 29-December 1. Topics selected for discussion are the American system of broadcasting, an evaluation of broadcasting from the point of view of the listener, educational broadcasting and the future of radio. George F. Zook, Ph.D., president of the American Council on Education, Washington, D. C., will again be chairman of the conference and Clarence S. Marsh, L.L.D., Washington, D. C., is executive secretary.

Twenty-five Thousand Persons Sterilized—The Human Betterment Foundation of California announced in a recent report that up to Jan. 1, 1937, a total of 25,403 sterilizations had been performed in state institutions under state laws in the United States. This was an increase of 2,241 over the total announced the previous year. These figures do not include operations in state institutions in states that do not have sterilization laws, the report points out, or operations that are primarily therapeutic, not eugenic in purpose. Twenty-nine states now have sterilization laws, the most recently enacted being that of Georgia. California, whose law was enacted in 1909, has performed the largest number of sterilizations, 11,484. Virginia is next with 2,634.

Aviators Vaccinated Against Yellow Fever—The Pan American Sanitary Bureau recently concluded arrangements with the Pan American Airways whereby all flying personnel will be vaccinated against yellow fever and all passengers will be required to record where they have spent the six days previous to embarkation in an effort to prevent transportation of the disease by air. This program was begun several months ago in Rio de Janeiro under the auspices of the U. S. Public Health Service (*THE JOURNAL*, June 19, p. 2149). It is now announced that a specially trained officer of the service will be detailed to Cristobal, Canal Zone, and Lima, Peru, and later to Miami, Fla., and Brownsville, Texas, to vaccinate the personnel of the air lines at those points. Each passenger will be

requested to fill out a standard form "Certificate of Origin of Passenger, which asks for localities visited or resided in for six days prior to embarkation." This period, plus the time consumed on the voyage, gives a fairly wide margin of safety, it is believed. In cases in which passengers have come from areas actually infected and the six day period of incubation since last possible exposure has not been completed on arrival at destination in the discretion of the quarantine officer the passengers may be placed in open surveillance observation or detention. Persons who can present satisfactory evidence of having had yellow fever or who can present certificates of vaccination will not need the certificate. The Rockefeller Institute for Medical Research will supply the vaccine from its laboratories in New York and Rio de Janeiro. As an additional precaution the planes are to be fumigated during the night with an insecticide and thoroughly ventilated in the morning before the embarkation of passengers, according to the agreement, published in *Public Health Reports* July 30.

Medical Bills in Congress—*Changes in Status* S 1077 has been reported to the House, with amendments proposing, among other things, to confer on the Federal Trade Commission jurisdiction over the dissemination of false advertisements with respect to food drugs, devices and cosmetics. S 1567 has passed the House proposing to permit the government to produce and sell under regulations approved by the President, helium for medical use. S 2970 has been reported to the Senate, proposing to reorganize the agencies of the government to extend the classified civil service and to establish a General Auditing Office and a Department of Welfare. The Secretary of Welfare, it is proposed will administer among others the laws relating to public health and sanitation. H Res 325 has passed the House authorizing the House Committee on World War Veterans Legislation to make a comprehensive survey of veterans hospitals to determine, among other things what further hospital facilities are needed. The committee will not later than Jan 3, 1938, report its conclusions to the Congress in the form of a bill or otherwise as it may deem necessary. H R 2711 has passed the Senate, with amendments, proposing to create a Division of Water Pollution Control in the United States Public Health Service. H R 8245 the third deficiency appropriation bill, has passed the Senate. The bill appropriates \$400,000 for the National Cancer Institute \$200,000 of which is to be available for the purchase of radium. The bill also authorizes the President to allot to the Public Health Service not to exceed \$200,000 to be used to continue the operation of the Hot Springs Transient Medical Center Infirmary at Hot Springs National Park, Ark. A further appropriation of \$50,000 is contained in the bill to enable the American Printing House for the Blind more adequately to provide books and apparatus for the education of the blind. **Bills Introduced** H R 8250, introduced by Representative Somers, New York, proposes to authorize an annual appropriation of \$5,000,000 to be allotted to the states for the study prevention control cure and eradication of syphilis. Plans must be submitted to the Surgeon General of the Public Health Service for approval before a state may obtain an allotment. S 2931, introduced by Senator Caraway, Arkansas proposes to authorize the Secretary of the Treasury to determine the total amount collected by the government from each physician during the period June 1, 1920, to June 30, 1931, for the privilege of prescribing the hot waters from the Hot Springs National Park and to refund to each physician the total amount so determined to have been collected from him with the proviso that no physician shall be repaid more than the sum of \$660. H Res 271, introduced by Representative Collins, Mississippi, proposes to establish a select committee of the House of Representatives to study laws and regulations pertaining to the general welfare of Indians and to require the committee to report the results of its investigations to the House on or before May 1, 1939. The first session of the Seventy-Fifth Congress adjourned sine die August 21. Legislation then pending before the Congress will retain its legislative status and may be acted on when the Congress convenes, Jan 3, 1938.

CANADA

Personal—Dr. Daniel Nicholson assistant professor of pathology at the University of Manitoba, Winnipeg has been promoted to the professorship of pathology, succeeding Dr. William Boyd who recently went to the University of Toronto as professor of pathology.

Graduate Courses—St. Michael's Hospital, Toronto will give a graduate course in medical subjects September 13-18. The University of Toronto Faculty of Medicine, Toronto is offering a course on physical and manipulative therapy and one on cardiovascular disease beginning September 20 and last-

ing a week, and a course on fractures for a week beginning September 27. The third annual refresher course will be presented at the University of Western Ontario, London, September 13-17, covering surgery, medicine, obstetrics and gynecology, and pediatrics.

LATIN AMERICA

Orthopedic Meeting in Brazil—The second congress of the Brazilian Society of Orthopedic Surgery and Traumatology was held in Rio de Janeiro, July 1-4. Among the speakers were Drs. Enrique Lagomarsino, Buenos Aires, Argentina on 'The Technic and Latest Apparatus for Treatment of Fracture of the Neck of the Femur', Fred H. Albee, New York, 'The Importance of the Lever at the Top of the Femur as a Stabilizing Influence and Its Restoration', Jose Luis Bado, Uruguay, 'Treatment of the Supracondylar Fracture of the Humerus', B. Valentin, Hannover-Kleefeld, Germany 'Systemic Diseases of Bone' and 'Congenital Anomalies of the Spine'.

FOREIGN

Personal—Prof. James H. Dible, professor of pathology in the University of Liverpool has been appointed to the chair of pathology in the British Postgraduate Medical School. Prof. Jacques Parisot, Nancy, France has been elected chairman of the Health Committee of the League of Nations to succeed Dr. Thorvald Madsen, Copenhagen.

Symposium on Rheumatism—The French League Against Rheumatism will hold its annual international symposium on rheumatism October 9 in Paris. There will be a clinical meeting in the morning at the Hopital Saint-Antoine and a scientific meeting in the afternoon at the Faculte de medecine. Details may be obtained by writing to Permanence de la Journee du Rhumatisme, 23 rue du Cherche-Midi, Paris VI.

Cholera in Hong Kong—An epidemic of cholera was reported from Hong Kong August 11 and more than 200 deaths had occurred up to August 20 according to the New York Times. Other outbreaks were reported from Macao, a Portuguese colony, and Canton. Hong Kong was reported to be crowded with refugees from the war zone. Inoculations of all new arrivals was required and vaccine for 250,000 injections was shipped from Singapore August 20. A report of that date said that health officers believed the epidemic had reached its peak and that it was confined mostly to the poorer Chinese.

Deaths in Other Countries

Prof. John Gordon Thomson, professor of medical protozoology, London School of Tropical Medicine and Hygiene died in London August 14, aged 60.

CORRECTION

Assistant Professor of Radiology—In a news item announcing recent appointments at Vanderbilt University School of Medicine, Nashville in THE JOURNAL August 7, page 440 the title of Dr. Herbert C. Francis should have been given as assistant professor of radiology.

Government Services

Changes in Public Health Service

Passed Asst. Surg. Erwin W. Blatter relieved at Ellis Island, New York and assigned to duty in the American consulate, Oslo, Norway in connection with the medical examination of aliens. Passed Asst. Surg. Harold L. Lawrence relieved at Oslo and assigned to duty in the American consulate, Berlin, Germany for the examination of aliens and the enforcement of quarantine procedures. Surg. Walter G. Nelson relieved at Berlin and assigned to Paris, France as relief officer in connection with the examination of aliens and the enforcement of quarantine procedures.

Examination for Commission in the Navy

Examinations for commission in the medical corps of the U. S. Navy and for appointment as interns will be held at all naval hospitals and at the naval medical school, Washington, D. C., October 11. Candidates for admission must be between the ages of 21 and 32 years at the time of appointment and graduates of or senior medical students in class A medical schools. Additional information may be obtained from the surgeon general, U. S. Navy, Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

War as a Disease

In a recent address to the Royal Institution of Great Britain, Lord Horder declared that war is "the greatest of all modern diseases, though it is primarily a disease of the mind and not of the body. It has existed since the race began, but its casualties were formerly trivial by comparison with those due to ordinary diseases. Today the proportions are reversed. The great war cost us 700 000 lives and 2 500 000 total casualties."

Science has reduced enormously the casualties due to the attack of the microbe on man but science has increased in much greater proportion the casualties due to the attack of man on man. The danger of another great war is never far from the thoughts of Europeans, and measures for averting that catastrophe are a constant preoccupation of England. It is therefore not surprising that a movement has arisen in the medical profession, which has such a special experience of the horrors of war, to play a part in its prevention. An organization of physicians called the 'Medical Peace Campaign' has therefore been formed. It holds meetings and publishes a bulletin. It has adopted the program of the International Peace Campaign, of which the main points are (1) recognition of the sanctity of treaty obligations, (2) reduction and limitation of armaments and (3) strengthening of the League of Nations for the prevention of war.

At the recent annual meeting of the British Medical Association, a resolution was moved that the council be asked to appoint a committee to consider and report on the psychologic causes of war and to press for an international section under the Health Organization of the League of Nations to deal with the psychology of war, on similar lines to the section now dealing with epidemiology. Reference was made to a committee of the Netherlands Association appointed six years ago with a similar purpose. Objection was made that any effective action must be international and an amendment to that effect was carried. The resolution, modified as follows was then carried: "That the Council be asked to press for an international section, under the health organization of the League of Nations to deal with the psychology of war on similar lines to the section now dealing with epidemiology."

Pharmaceutical Conference Criticism of the Politicians

At the British Pharmaceutical Conference Mr. T. E. Lescher, managing director of a well known firm of manufacturing pharmacists, said in his presidential address that our present system of allowing any one to handle the majority of drugs and medicines, on paying of a dollar license annually, encouraged the exploitation of the public by the distribution of "cure-alls" without the slightest knowledge of their properties on the part of the vendor. The official attitude in its most debased form was shown recently in the report of the Select Committee of the House of Commons on Medicine Stamp Duties. The committee recommended a sales tax on medicines and even on foods and beverages, if claimed to be beneficial to health. That in a so called enlightened age a body of public men should suggest that the state was justified in taxing substances used in ill health was unbelievable. Before 1914 under our *laissez faire* policy the fine chemical industry in Britain, particularly on the organic side was not extensive, and we were largely dependent on imported products. War experience gave British chemists their opportunity, and the manufacture of fine chemicals and biologicals today was on a scale sufficient to meet the require-

ments of our trade both at home and overseas. The advance of knowledge in recent years made it safe to prophesy that further important discoveries were just round the corner and that biologic and therapeutic products would increase in variety.

The Treatment of Pleural Effusions

In a discussion at the Royal Society of Medicine on the treatment of pleural effusions Dr. Burton Wood said that many effusions required no active treatment. They were benign and might even be protective in their effect. Thus a pleural effusion was the commonest manifestation of pulmonary tuberculosis in childhood, when it appeared to be analogous to other reactions of allergic type seen in child "contacts." Such effusions had little effect on health, sometimes disappeared rapidly, and were rarely followed by parenchymatous disease. Some of the adolescent pleurisies he thought were of a similar type. For this reason he held that a young person with a 'simple' pleural effusion and possibly in a hypersensitive state, should not be exposed to the risk of further infection for example in a sanatorium cubicle shared by a bacilliferous patient.

What was the after-history of patients whose lungs were apparently sound at the time of occurrence of a simple effusion? It had always been taught that the expectation of subsequent phthisis was from 40 to 50 per cent, but recent figures from Scandinavia suggested that 90 per cent of the patients made a lasting recovery. Time had not enabled Dr. Wood to make an exhaustive inquiry and he could not claim statistical accuracy, but in a series of thirty of his own cases, comprising young persons of the working class (from 15 to 35 years of age at the onset) twenty-seven have remained well and of the three who had died all had bilateral pleurisy.

If effusion is suspected, x-ray examination should precede exploration. Blind tapping was justifiable only for the relief of urgent symptoms, and haphazard aspirations in the front bedroom were to be deprecated. If the disease ran a favorable course the fluid would be absorbed spontaneously but if of less benign type aspiration would be followed by fresh outpouring of fluid, which would thicken as aspirations were repeated. The end result might be a chest still full of fluid, but empyematous fluid. The existence of a tuberculous focus in the underlying lung was often assumed and this had given rise to the practice of air replacement and the maintenance of the pneumothorax for some months to protect the lung. This treatment was based on speculation unless the effusion was known to cover diseased lung. When the large size of an effusion caused mediastinal displacement or distress air or oxygen replacement was of course necessary but Dr. Wood thought it useless to try to prevent reaccumulation by pneumothorax. If hectic fever persisted an aspiration would sometimes be followed by a fall in temperature. It was justifiable to try the effect of this with or without replacement, but repeated aspirations were undesirable. When fluid persisted for a month or more it was customary either to remove a few ounces to encourage absorption of the remainder or to try to secure a dry pleura. It was true that fluid if left would ultimately give rise to pleural thickening but an obliterative pleurisy, with the fibrosis to which it gave rise, was a conservative process. Fibrosis began where tubercle ended.

With regard to the effusions complicating artificial pneumothorax many of these were benign in their effect. An incomplete collapse was sometimes converted into a complete collapse, and a cavity held out by adhesions closed before their section could be considered. Sometimes an effusion rapidly filled the pleural space and it was tempting to replace it by air in the hope of maintaining a controlled collapse. But replacement was usually followed by reaccumulation, and repeated aspirations brought the risk of empyema. If one or two air replacements failed, Dr. Wood thought it better not to continue intervention. A natural serothorax was a good substitute for a pneumothorax and the effusion was slowly absorbed.

First International Congress of Industrial Medicine

The first International Congress of Industrial Medicine was held June 2-6 in Paris. Following an introductory address by Professor Carozzi of Geneva on the important influence of the International Labor Bureau of the League of Nations on legislation in occupational diseases and factory sanitation, the various papers were grouped under four headings: group 1 teaching the subject of industrial medicine, group 2 pathologic aspects of industrial medicine, group 3 prophylaxis and treatment, group 4, legislation.

TEACHING INDUSTRIAL MEDICINE IN FRANCE

A paper on teaching methods as employed in the Paris Medical School was read by Professors Duvour and Rene Fabre. A distinction was made between preventive social medicine, which is a branch of hygiene, and technical social medicine, which in France includes industrial medicine and is considered a branch of legal medicine. The course consists of forty lectures, including (1) generalities and comparative legislation of occupational diseases, (2) study of the latter caused by chemical, physical, plant and bacterial agents, (3) clinical syndromes of occupational origin, (4) diseases in miners, in metallurgical, electrical and chemical industries and in those working at high altitudes, engaged in farming and fishing, and (5) sports at factories. These conferences are supplemented by laboratory work in industrial toxicology for those who wish to receive a degree in industrial medicine.

PATHOLOGIC ASPECTS OF INDUSTRIAL MEDICINE

In group 2 the first paper was by Professor Loeper and Dr Gilbrun, on professional oxycarbonism. In estimating the carbon monoxide content of the blood by the Nicloux method, the authors were able to detect a chronic carbon monoxide intoxication in five gas works employees who complained of headache and digestive disturbances and who were anemic.

Dr Kohn-Abrest said that a certain percentage of carbon monoxide is normally found in the blood. On the other hand, he has noted what would seem to be paradoxical, that in acute intoxication all the carbon monoxide is eliminated in a few hours, whereas in a chronic intoxication small amounts can be found for months. There seems to be a difference of mechanism of fixation by the blood in acute and chronic cases.

Dr Sezary presented a paper on occupational skin lesions and proposed the following classification as being of prognostic, preventive and therapeutic interest. He first distinguished dermatoses due to physical, chemical, microbic and parasitic agents which can involve large groups of workers employed under the same physical conditions. Second, dermatoses due to chemical plant or microbic agents which affect only those especially predisposed. This predisposition can be demonstrated by epidermal reactions, which have much value in the diagnosis of this group of dermatoses.

The problem of intolerance in industrial medicine was the subject of a paper which Drs Tzanck and Sidi presented. They said that a distinction should be made between intoxications due to the direct action of the poison and the individual reactions of intolerance, as regards legislation in legal medicine. They explained the problem of intolerance and distinguished its clinical, evolutive and biologic variations, which permit clearing up our conceptions of idiosyncrasy, anaphylaxis and hypersensitivity. All these have certain features in common. They are all individual, all vary according to the environment in which they occur, and all are different from intoxications. In the discussion of this paper, Duvour emphasized the importance of predisposition. He agreed with the authors in considering intolerance of intoxication as funda-

mental. The tolerant worker can resume his occupation after an intoxication provided no serious organic sequels persist, whereas the worker who has a lack of tolerance for a certain substance must be definitely excluded from taking up the same work, no matter how mild the first intoxication may have been.

Factory work in relation to pregnancy was discussed by the obstetrician Professor Brindeau. Certain occupations that involve prolonged standing, intense vibrations or bending over should be forbidden during pregnancy. Especially to be avoided is work with aniline dyes. Excessive work or intoxications can be followed by abortion, premature labor or the birth of undersized children. The present laws are inadequate. Women during pregnancy ought not to work in a factory and should restrict their activities to housework, but the allowances paid by the state are insufficient and hence it becomes the duty of every employer to interest himself in the protection of woman workers during pregnancy.

In a paper on latent benzoinism in factories around Paris, Dr Tara stated that where benzene is used he had observed an asthenia syndrome associated with blood changes in the form of a mild anemia, leukopenia, agranulocytosis with eosinophilia and prolonged bleeding time. Usually there is inadequate ventilation in such factories.

The question of traumatic arthritis of the elbow in workers who use hammers or pneumatic tools was taken up by Drs Belot and Nahan. They found joint changes similar to those observed in arthritis deformans. Clinically, only slight pain and stiffness of the elbow joint is complained of. Radiography often reveals marked changes such as enlargement of the diaphyses, osteophytes and intra-articular detached pieces of cartilage. The incidence of such changes in workers is very small, only 2 per thousand according to Rostock. In the discussion, Dr Desoille maintained that such joint sequels were often the result of improper use of the tools. This was also Dr Koelsch's opinion.

PROPHYLAXIS AND TREATMENT

Dr Kohn-Abrest reported that great progress had been made in purifying the air in most factories, as the result of frequent analyses for carbon monoxide and dioxide, combustible gases and chlorine derivatives of hydrocarbons by the toxicology laboratory of the city of Paris.

Dr Barthe spoke on the duties of a physician engaged in the practice of industrial medicine. The chief objective should be prevention, next he should act as an adviser in questions involving safety, hygiene and scientific organization of the daily work. There should be a team composed of the physician, engineer, sanitary technician and psychotechnician to study every problem involving the safety and health of the employees. Arrangements must be made with the nearest hospitals, dispensaries and social service organizations, in case the factory does not possess these.

Dr Lahy described the first laboratory of psychotechnic in France established by a large railroad company in 1931. This paper showed that the application of preliminary psychotechnical examination of candidates for positions had resulted in allowing the railroad to avoid placing 60 per cent of those tested in places where accidents were a potential factor and giving them other work.

Dr Marchandise of Belgium, in a paper on medicosocial aid for workers handicapped by cardiovascular disease, stated that the medical and social aspects of the question must be considered separately. A thorough preliminary examination of every worker must be made to permit adaptation of his duties to his physical forces. The best tests in addition to the physical examination, include the use of tachymetry to measure the rapidity of the circulation and radioscopic control of the aortic cardiac shadow. Workers with marked hypertension have a mortality coefficient much higher than those in the same con-

dition who are not obliged to work and hence can be properly cared for. A worker with hyposystole ought not to be allowed to work.

LEGISLATION FOR OCCUPATIONAL DISEASES

The first paper in group 4 was by Professor Ranelatti, who described the Italian laws for six occupational diseases: lead, mercury, phosphorus, carbon bisulfide, benzene and ancylostomiasis. The various diseases incident to coal mining are considered under industrial accidents. Concomitant with better organization a notable decrease has been noticed in the incidence of these occupational diseases, even in the case of lead poisoning.

Delegates from France and other European countries read papers on the legislation in their respective countries. Of interest was a statement by Dr. Bauer of Germany that there are now twenty-six occupational diseases which are indemnified in that country.

Specialists in Social Medicine

An organization known as the Social Insurance Medical Advisers and Inspectors held an annual meeting June 4-7 at Clermont-Ferrand, in central France. The two questions selected for discussion were (1) the role of medical control in social medicine in general and in social insurance in particular, and (2) treatment at health resorts of the socially insured. At the beginning, those who accepted these positions of advisory and inspection type in social medicine encountered a great deal of opposition on the part of their colleagues. The medical men who represented the interests of the caisses, or social insurance disbursing bureaus, were regarded as a sort of police force. At present thanks to the tactful and more ethical methods followed by most of the medical inspectors, this opposition has been overcome to a great extent. This is especially true of those inspectors who have had special training in their duties toward both the medical attendant and the insured.

The social role of the medical comptroller or inspector was defined as (1) search for social diseases and those incident to industrial medicine, and (2) close cooperation with all the government public health agencies, such as social hygiene, maternal and infantile protection and adaptation to vocations.

After the meeting, a number of health resorts in the vicinity of Clermont-Ferrand were visited in order to familiarize the medical officers of the social insurance with the advantages of sending the insured there for treatment.

The Evaluation of Radioactive Therapeutic Substances

Physical and chemical qualities of radioactive substances were discussed by Dr. S. W. Souci before the Medical Society of Munich. For the evaluation of the numerous radioactive products now on the market (natural and artificial radon-containing waters, radium compresses, radioactive ointments for the skin, radioactive fats and radioactive oils) and the apparatus (emitters, radonators, activators) designed to facilitate the administration of these substances an exact knowledge of radioactive decomposition is indispensable. The atomic fragments produced by these substances appear as alpha rays (positive charged helium nuclei) and beta rays (negative electrons). A third type, the gamma rays, consist of electromagnetic vibrations with great powers of penetration. Conversely, the penetrating capabilities of the alpha and beta rays are proportionately small. Since the rays are effective only if absorbed by the organism, the physiologic reaction is chiefly dependent on the density of the layers of tissue irradiated. There are three routine methods of the administration of radioactive waters: drinking, balneotherapy, and inhalation. The radon ingested if the water is drunk passes rapidly from the gastrointestinal

tract into the circulation and in a short while is given off by the lungs. By preliminary ingestion of a meal or by combining the radon with fats or active charcoal, the period during which the emanation remains in the organism may be increased. In contrast to radon, radium element remains retained in the body for a long period and comes to be stored in the bones. Cumulative storage of even small single doses can cause severe damage or even death after a long time. For this reason substances that contain radium are administered only after special precautionary measures have been taken. In balneotherapy, radon because of its solubility in water and lipoids can gain entrance to the organism through the skin as well as through the lungs and can thus become effective in sufficient concentration. At the same time there is formed on the cutaneous surface a radioactive deposit consisting of the products of radon decomposition, which gives rise to a secondary effect by its beta and gamma radiation. In view of the ubiquitous distribution of radium and its decomposition products many mineral and curative springs present some degree of radioactivity. Springs possessed of truly powerful radioactive properties are, however, rare. The radon content of radioactive water is still sometimes measured by the so-called mach unit in Germany and Austria. According to its definition this is a unit of concentration and not of quantity, yet the mach unit has been extensively but erroneously used as a quantitative unit as well. To avoid uncertainties only the international quantitative unit, the "microcurie" should be used; that is the amount of radon should be the equivalent of 1 microgram of radium, if, however, the term mach unit is applied, it is absolutely necessary that the relative value also be expressed. It is difficult to refer to a particular unit of concentration for therapeutic purposes. The German Society of Balneotherapeutics and Climatology about five years ago formulated guiding principles which placed the evaluation of radioactive therapeutic springs on a sounder basis by more precise definition of terms. According to the society no health resort can properly be designated a radium spa unless it has at its disposal natural radon or radium containing mineral waters the radioactive powers of which amount to at least 80 mach units or 10 (0.0000001 microgram) of radium per liter. Radioactive spring water bottled for shipment must at the time of consignment to sick persons still contain a minimal radioactive value of 800 mach units per liter.

Juvenile Delinquency

The fursorge-erziehung (juvenile delinquent bureau) undertakes the supervision and upbringing of juvenile delinquents and other young persons in need of strict supervision. According to official statistics there were on March 31, 1936 about 60,000 young persons in charge of the fursorge. In the year 1925 there were 100,000 of these minors dependent on public care but by the year 1933 this number had sunk to 52,000. The latest figure accordingly represents a new increase but this is explicable as chiefly due to changed prerequisites of commitment as well as to the increased birth rate of the post-war years. About 55 per cent of the delinquents are boys. The period of life covered by the activities of the fursorge has been somewhat shortened. Despite the decline in unemployment the proportion of unemployed among the fursorge's charges has risen again. The principal manifestation of delinquency among male minors that brings about commitment to the fursorge is in Prussia some offense against property, about 55 per cent of male delinquents are committed on these grounds. Sex delinquents constituted about 14 per cent of the male inmates; the number of vagrant minors increased by 45 per cent. Among the girls, sexual delinquency was the most frequent cause of commitment; it was the cause in 56 per cent of cases. The total expenditure of the fursorge-erziehung for the entire country amounted in 1936 after deduction of the

reimbursements and other income to 28,100,000 reichsmarks. The average annual gross amount expended per juvenile delinquent (without deduction of income) is 534 marks.

The Cancer Problem

Willy Baensch, professor of radiology at Leipzig, in a recent discussion of the cancer problem before the medical society of that city made several important observations. The abundance of new contributions to the literature on the causation and treatment of cancer is characterized by a wide divergence in attitudes, which range from cancerophobia and therapeutic nihilism on the one hand to optimistic claims of new methods of cure on the other. The number of fatal cancer cases in Germany at present may be estimated at from 80,000 to 100,000 and in the United States at about 125,000. A careful study of etiologic factors leads one to conclude that the production of cancer is not based on any single factor but on a multiplicity of factors. Certain irritations will produce cancer in one organism whereas a second organism subjected to identical stimuli will fail to manifest the disease. This susceptibility to cancer formation appears to be to some extent inheritable. The precancerous state of irritation among experimental animals may last from three to four months, as in the mouse, or one year, as in rabbits, whereas in man it may endure for about eight years. The irritant may be mechanical, such as chronic pressure of a dental prosthesis, eyeglasses or a pessary, chemical, as when cancers are produced by a known cancerogenic irritant substance or chemico-physical, as when the irritation is due to long standing injuries from lights and emanations. These two factors (predisposition and irritation) are ultimately combined with a third or liberating factor which is still unknown. Some believe in an invisible virus, which no one yet has been able to identify. One type of malignant neoplasm that may safely be ascribed to just such a virus is the Rous sarcoma of fowls. It seems probable that metabolic disturbances of organic function also play a part in the pathogenesis of cancer.

Graduate Medical Education in New South Wales

Graduate teaching in medicine has been carried out in Sydney for many years. Since 1900, courses have been arranged at intervals by the University of Sydney or the New South Wales Branch of the British Medical Association. In April 1929 the New South Wales Branch of the British Medical Association formed a standing committee of the Council for the organization of graduate work. This committee arranged a number of regular courses. In September 1932 the New South Wales Branch of the British Medical Association formed a committee, which after several years approached the University of Sydney with the idea of closer cooperation and Aug. 12, 1935 the senate adopted a new by-law for the establishment of a committee to be known as the New South Wales Post-Graduate Committee in Medicine. All money and property of the New South Wales Permanent Post-Graduate Committee, which reverted to the New South Wales Branch of the British Medical Association was presented by the branch to the University of Sydney for use by the new committee. In 1936 the New South Wales government, on the recommendation of the minister for public health, made a grant of the sum of £1,000 to the Post-Graduate Fund in Medicine for the purposes of the committee. The Post-Graduate Committee has a building at its disposal for teaching purposes and courses for graduates. The resources of the University of Sydney and many of the hospitals of New South Wales. Each year the committee holds a general revision course of instruction given at all the larger metropolitan hospitals and designed for general practitioners. Courses of a more special nature are arranged and week end

courses are held at country centers. Instruction for higher degrees and diplomas is provided. The committee also makes arrangements for residence at obstetric, children's and general hospitals, instruction in the diseases of children and infant feeding, attendance at clinics for the diagnosis and treatment of cancer and tuberculosis, and tuition in anesthetics. A feature of graduate education in New South Wales has been the organization of a special hospital for graduate teaching. Aug. 1, 1936, an act was passed reconstituting the Prince Henry Hospital. A board of directors of fifteen was appointed, whose duties are to conduct and maintain the hospital for the treatment of public, private and intermediate patients and to make such provision as may be necessary or desirable to enable graduate teaching and research work in medicine to be carried out at the hospital by or under the authority of the University of Sydney. The board may make provision for the training of medical superintendents, hospital managers, hospital secretaries, hospital matrons, nurses, masscurs, almoners, dietitians, x-ray technicians and pathology technicians. The Prince Henry Hospital is undergoing a period of reconstruction and development preparatory to the introduction of regular graduate instruction and research, which it is hoped will start during the present year.

Medical Research in Australia

Prof. Frederic Wood Jones, professor of anatomy at the University of Melbourne, takes rather a pessimistic view of the problem of medical research in Australia. Professor Jones has been a member of the staffs of universities in Europe, America and Australia, and subsequent to the preparation of his report he resigned his chair in Melbourne to take up a similar position at the University of Manchester, England. As a reason for this action he stated that the opportunity for research work is too restricted in Australia, greater opportunities being given in overseas countries. Professor Jones is one of the most prominent figures in Australian academic medicine. A brilliant orator, a forceful writer and an original thinker, he will be a serious loss to medical education in Australia. He considers that the best research workers are being lost to Australia through lack of suitable prospects of academic research. The best type of research worker is he who from his student days is set in his idea of becoming a research worker—a man to whom the lures of successful practice mean nothing but who is determined on investigation for its own sake. Australia is losing men of this type in a small but continuous stream. One of the difficulties in Australia is that the routine teaching and administrative duties that have to be undertaken by the staff of the medical schools is so pressing that, with the best will in the world, it is in many cases impossible for research work of any real importance or any real continuity to be carried out. The demands made on the occupant of a chair for doing work outside his teaching routine are mainly those of solving problems for medical men practicing in the state and in answering innumerable letters seeking information about all sorts of matters usually unrelated to the professional sphere of the recipient.

Research of national importance must have two prerequisites. The first is coordination of effort, and the second is direct leadership. Professor Jones doubted whether, in the absence of coordinated team work, it was wise to endow with large sums of money the prosecution of such studies as cancer research in Australia. Close coordination between the medical biologist, the chemist and the physicist within a single research institute is almost essential if a successful attack is to be made on the problem of malignancy. It would be one of the miracles in the history of medical science if the solution of the problem should be revealed to any isolated investigator no matter how great his scientific attainments or how ample the funds at his disposal. Until team work is better organized than it is today,

in Australia it would be wise to give preference to the "individual" type of investigation in the allocation of research grants. Meanwhile, every effort should be made to create conditions that would make well coordinated team work a possibility in the Australian medical schools. Another handicap to medical research in Australia is the lack of trained technical assistants. The present meager finance devoted to the teaching departments of medical schools does not permit of proper advancement to those who take on this type of work as a life occupation. In conclusion, Professor Jones considers that it is a waste of money to attempt to create a research worker to deal with a specific problem, but it is always a wise investment to place the real research worker in a position of comparative freedom from urgent financial problems.

Abortion in New Zealand

At the request of the obstetric and gynecologic section of the New Zealand Branch of the British Medical Association, the prime minister of New Zealand set up a commission to inquire into the incidence of septic abortion in New Zealand. A questionnaire was sent to all the executive officers of the divisions of the British Medical Association of New Zealand. These were collated by the obstetric section of the association, and a positive answer was given to the question "Do you consider that induction of abortion is extensively practiced in New Zealand?" In reply to the question "What practice do you consider to be the more common?" the consensus was that the single woman resorts to the abortionist but the married woman, on account of the expense, more commonly attempts self induction. Drug taking is largely practiced in the first instance. This usually fails and is followed by other methods of self induction, such as the insertion of an instrument into the uterus, purgation combined with vaginal douching, and violent exertion. Drugs alone are seldom effective unless taken in doses that are dangerous to the mother. Criminal abortion is usually carried out by the introduction of a catheter into the uterus. Other methods adopted were the injection into the uterus of fluids such as soap solutions, saponated solution of cresol or iodine, and the use of tents. It was stated that septic abortion usually occurs in the induced class, especially the instrumentally induced group but that there were cases of sepsis following spontaneous abortion. The commission of inquiry in its final report estimated that at least one pregnancy in every five ends in abortion. About 66 per cent of these are unethically induced, either through the agency of criminal abortionists or by self induction. Deaths from septic abortion occur almost entirely in such cases. These deaths have greatly increased in recent years and now constitute one fourth of the total maternal mortality. In some districts it amounts to nearly half of the total maternal mortality. According to comparable international statistics, New Zealand has one of the highest death rates from abortion in the world. The main causes for abortion are (1) economic and domestic hardship (2) changes in moral and social outlook (3) pregnancy among the unmarried and (4) fear of childbirth. Suggested remedies to overcome these causes are: 1. Financial, domestic and obstetric help provided by the state. 2. The correction of the outlook of women today which expresses itself in a demand for a right to hunt or to avoid a family. The widespread half knowledge of birth control methods encourages a false sense of security, these ineffectual methods often fail and the temptation to abortion then follows. 3. More careful education of the young in matters of sex. The advertisement of the sale of contraceptives to young people should be prohibited but at the same time there should be a more tolerant attitude on the part of society toward the unmarried mother and her child. 4. Education of the public with regard to the fact that New Zealand now has a very low death rate in actual birth and that relief of pain in labor is largely used. Further efforts in the direc-

tion of the relief of pain should be explored. The public should be educated to the responsibilities and privileges of motherhood and the advisability of self discipline in certain directions. Knowledge of birth control should be given through responsible channels, mainly through well informed doctors and to a certain extent through clinics associated with the hospitals. Through women's social organizations, the womanhood of New Zealand should be appealed to, and the selfish and unworthy motives which have entered into family life should be corrected. The sale or distribution of contraceptives should be restricted to practicing chemists, doctors, hospitals and clinics and public advertisements of contraceptives should be prohibited. No alteration of the law as regards abortion was recommended and it is considered that when the reasons for the operation are valid the doctor runs no risk of prosecution. The committee strongly condemned any suggestion of legalization of abortion for social and economic reasons. It was realized that the legalized performance of the operation by doctors in hospitals might reduce the incidence of criminal abortion and deaths from septic abortion but that this procedure could not be justified on account of its association with grave moral and physical dangers. The committee realized that it was unable to put forward a complete and certain solution of this grave problem, but the full publicity given to the investigation would, it was hoped, awaken the public conscience, and the ultimate issue would rest with the attitude and the action of the people themselves.

BUCHAREST

July 26, 1937

The Rumanian Medical Association

The annual congress of the Rumanian Medical Association was held July 18 in the palatial residence of the association in Bucharest, under the presidency of Prof. Peter Tomescu. In his address, Tomescu said that one object of these annual congresses is to examine the social and material position of the medical profession and to search for the best way to adapt itself to the present social scheme. The association is gaining in importance in the eyes of the government and now must assume the task of preparing an adequate plan for the hygienic organization of the whole country. In recent years the association has dealt more and more intensively with the health of the villages. What has been accomplished in this field is due in the main to the work of the minister of health, Dr. Costinescu.

The congress voted approval of the following resolutions: 1. Military field physicians shall be appointed in peace and also in war, according to their special abilities and ages. Reserve physicians shall be given rank corresponding to their civilian occupation. 2. Toward the elimination of obstacles to medical practice, the association will fight for a better distribution of physicians, for it is not satisfactory that in some cities the ratio of physicians to population is 1:300 while in certain rural districts the ratio is one physician to 19,000 people. 3. There should be a revision of foreign medical diplomas obtained since the World War. 4. A sickness insurance bureau for physicians should be organized. 5. Physicians employed in certain public offices should not be dependent on politics but should be appointed definitively and for life for only so can they perform their duties with full devotion. Professor Guie, representing the minister of health, stated that it has become almost a tradition since 1910 that the minister fulfils the wishes of the medical association. While in 1933 the total number of rural physicians was 933, this number is now 1,600. The government has tried to improve the situation of rural doctors and at present they enjoy a salary which ensures them a living worthy of their standing. In the last three years, 550 dispen-

saries were opened and five new foundling houses were established. The budget of the ministry of health approaches two milliard lei (\$20,000,000).

The three 10,000 lei prizes offered by M. Cantacuzino, proprietor of the huge serologic laboratory in Bucharest were awarded to P. Ramneantu for his elaborate charts showing the growth, weight and state of nutrition of Rumanian children between 5 and 15 years of age to R. Patroianu for his work on latent tuberculous infection in children vaccinated with BCG and to N. Paraschivescu for his study "Contributions to the Study of Transmissible Paralysis."

Abramovici and Moisesescu read a paper on the present difficulties of medical practice. The trend to socialization and nationalization wholly ruins private medical practice. Social insurance and other collective activities founded for the purpose of supplying cheap medical service more and more constrict the field from which private practitioners gain their patients. They offer as a remedy the regulation of gratuitous medical attendance, the awakening of interest in rural medical practice, the extension of social insurance to the villages, limitation of the number of physicians who may settle in towns and cities, the extermination of illegal practice, the prohibition of advertising by charlatans in the newspapers and the augmentation of the number of physicians employed in hospitals.

After the conclusion of the work of the congress members of the association visited the Central Clinic for Mental and Nervous Patients which is under the direction of Professor Tomescu, president of the congress. The results of treatment were shown on an instructive film. After the inspection of the clinic, Professor Tomescu entertained the members.

The Late John D. Rockefeller

All medical journals in Rumania have printed editorials on the passing of John D. Rockefeller, expressing their deep feeling on his death. In one year the Rockefeller Foundation granted about 30,000,000 lei for the promotion of health institutes in Rumania. With this sum a malaria station has been built and equipped in the most modern way, the school for nurses in Cluj was enlarged by several new groups of buildings, laboratories were established and the Social Rumanian Institute was built. Funds were allotted to the Bucharest Demographic Institute, the Bucharest Institute of Hygiene and the Central Sanitary Institute. Even more recently the Rockefeller Foundation granted money for the erection of an institute in Jassy for the study of scarlatina.

Marriages

ANTHONY MILLS PERNETTI Paterson N. J., to Miss Louise Joan Cerabone of La Grangeville, N. Y. at Sylvan Lake N. Y., July 29.

KENNETH COSTICH Rochester, N. Y., to Miss Margaret Camilla Kirkland of Durham, N. C. June 14.

EDWIN EMMONS CORCORAN Lancaster S. C. to Miss Dorothy Rowe Lucas of Charleston, June 5.

ROBERT WESLEY BRADON JR. Martin, Tenn., to Miss Mary Frances Harris of Memphis in March.

ION ATHALSTEIN EILDFELL to Miss M. Meech both of Winnipeg Manit., Canada July 10.

ELMER SHEPMAN ALLEN JR., Arcola Ill., to Miss Jane Chloe Jarman in Oklahoma City in June.

FRED I. CRISTROM to Miss Myrtle Helm Puckel both of Rockford Ill. in June.

LEON MATHON COTTRELL to Mr. Charles Henry Birdsall, both of New York June 26.

LESLIE M. CHAPMAN, Boston to Miss Virginia M. Gies of Detroit May 29.

WILLIAM H. ALTIER to Miss Pauline Kerr, both of Fowler, Ind. June 23.

Deaths

Joseph Augustus Blake, Litchfield, Conn., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, assistant demonstrator in anatomy in 1891, instructor in surgery in 1900 and professor of surgery, 1903-1913, at his alma mater, member of the American Surgical Association, Society of Clinical Surgery and the American Association of Anatomists, fellow of the American College of Surgeons, corresponding member, Societe de Chirurgie, Paris, surgeon to the American Ambulance, Neuilly, France, August 1914-October 1915, head of the British base hospital at Ris Orangis, October 1915-March 1917, the American Red Cross Hospital in Paris, April Oct 31, 1917, appointed commanding officer and surgeon in chief to the American Red Cross Military Hospital, number 2, Paris major in the medical reserve corps in 1917 and in 1918 was made a colonel in the medical corps of the U. S. Army, in 1917 was decorated by the Legion of Honor of France and in 1922 was made an officer, in 1919 received the Distinguished Service Medal, consulting surgeon to St. Luke's, Roosevelt New York Orthopedic, Beekman Street and Presbyterian hospitals, New York St. John's Riverside Hospital, Yonkers and Tarrytown (N. Y.) Hospital, on the editorial board of the *American Journal of Surgery* from July 1926 to December 1927, aged 72, died, August 12, of cerebral hemorrhage.

Judson Daland Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1882, formerly professor of clinical medicine at his alma mater, emeritus professor of medicine at the Medical Chirurgical College, Graduate School of Medicine, University of Pennsylvania, fellow of the American College of Physicians, member and past president of the American Clinical and Climatological Association, president of the Philadelphia Institute of Medical Research, surgeon with rank of lieutenant commander in the Naval Coast Defense Reserve in 1917, editor of *International Clinics*, 1891-1899, consulting physician to the Jewish and Misericordia hospitals and the Norristown (Pa.) State Hospital, aged 77, died, August 14 in Ventnor, N. J.

Henry Louis Hilgartner Austin, Texas, University of Maryland School of Medicine, Baltimore, 1889, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, on the staffs of the Texas Deaf Dumb and Blind Institute, Brackenridge and St. David's hospitals and the Seton Infirmary, consulting eye, ear nose and throat surgeon and examiner U. S. School for Aeronautics, during the World War, aged 68, died, June 9, in Atlantic City, N. J. of coronary occlusion.

Max Lyon Folk Chicago, Chicago College of Medicine and Surgery, 1917, assistant professor of ophthalmology at the University of Illinois College of Medicine, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, served during the World War attending ophthalmology to the Michael Reese Hospital and Research and Educational Hospital of the University of Illinois, aged 47, died June 7, of adenocarcinoma of the stomach.

Ernest Ustick Buckman Wilkes-Barre Pa. University of Pennsylvania Department of Medicine, Philadelphia 1897, member of the American Academy of Ophthalmology and Oto-Laryngology and the American Otological Society, fellow of the American College of Surgeons, past president of the Luzerne County Medical Society, member and past president of the board of directors of the Wilkes-Barre General Hospital, aged 73, died June 1 of coronary thrombosis and arteriosclerosis.

Burton Wilson Mack, Chicago, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1903, member of the Illinois State Medical Society, fellow of the American College of Surgeons, assistant clinical professor of surgery Loyola University School of Medicine, on the staff of St. Ann's Hospital, aged 66, died June 7 at his home in Oak Park Ill., of carcinoma of the prostate.

Earl Bertrand Sweet, Los Angeles University of Pennsylvania Department of Medicine Philadelphia 1898, member of the California Medical Association, fellow of the American College of Physicians, served during the World War on the staff of the Los Angeles General Hospital, aged 62, died May 22 of carcinoma of the colon and bronchopneumonia.

Julius Joseph Leyko Baltimore University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1927, fellow of the American College of

Surgeons instructor in surgery at his alma mater, on the staff of the Mercy Hospital aged 33 died suddenly, June 8 of an accidental overdose of sodium amytal

Herman William Froehlich * Minneapolis Minneapolis College of Physicians and Surgeons 1906 fellow of the American College of Surgeons, member of the staff of St Barnabas and St Andrews hospitals was a trustee of the Concordia College St Paul, aged 57 died, June 14, of coronary occlusion

Joseph Patrick Burns * Philadelphia University of Pennsylvania Department of Medicine Philadelphia, 1906, served during the World War formerly on the staffs of St Vincent's and St Agnes hospitals, aged 76, died, June 4 in the Misericordia Hospital of traumatic shock, due to a fall

Harry Garland Timbres, Media, Pa., Johns Hopkins University School of Medicine Baltimore 1928 at one time assistant in biostatistics at Johns Hopkins University School of Hygiene and Public Health, aged 38, died, May 12, of typhus while at Marbunstroy, near Kazan, Russia

Edward Joseph Morris, Brooklyn University and Bellevue Hospital Medical College 1899 fellow of the American College of Surgeons served during the World War, aged 66, gynecologist and obstetrician to the Holy Family Hospital where he died, May 23, of coronary thrombosis

Charles Fuller Quinn, Cherokee Iowa, Sioux City College of Medicine, 1896 member of the Iowa State Medical Society county coroner and city health officer aged 78, on the staff of the Sioux Valley Hospital where he died, June 8 of carcinoma of the stomach and pancreas

William James Fleming, West Allis, Wis., Marquette University School of Medicine, Milwaukee, 1916 member of the State Medical Society of Wisconsin, served during the World War aged 48 died June 4 of cerebral hemorrhage and essential hypertension

Frank Aloysius Conlon * Lawrence, Mass Harvard University Medical School, Boston, 1904 member of the American Academy of Ophthalmology and Oto-Laryngology fellow of the American College of Surgeons, aged 56 died, June 23 of acute coronary occlusion

Walter William Peck, Darlington Wis., Rush Medical College, Chicago, 1883 past president and secretary of the Lafayette County Medical Society at one time mayor and president of the school board aged 77 died, June 13 of acute dilatation of the heart

James McElroy Fetterman * Pittsburgh Western Pennsylvania Medical College, Pittsburgh 1900 staff psychologist for the board of education aged 62 died June 1 in the Homeopathic Hospital of perforation of the common bile duct with biliary abscess

John Alfred Workman * P A S, Lieut, U S Navy, Hahnemann Medical College and Hospital of Philadelphia 1930 entered the navy in 1930 aged 31 was drowned when he was lost at sea from the S S *President Polk* April 3 near Honolulu Hawaii

William A Swope, Wheeling, Mo., University of Louisville (Ky) Medical Department 1885 aged 76 formerly on the staff of the Chultheote (Mo) Hospital where he died May 24 of heart disease, as he was preparing a patient for an operation

John Clark Jones, Brookline, Mass Rush Medical College Chicago 1881, Bellevue Hospital Medical College, New York 1882 Harvard University Medical School Boston 1895, member of the Massachusetts Medical Society, aged 80 died, June 17

Charles Howard Jameson * Hays, Kan., Washington University School of Medicine St Louis 1907 fellow of the American College of Surgeons on the staff of St Anthony's Hospital aged 50, died June 14, of acute dilatation of the heart

Thomas Enoch Steen, Florence Miss University of Nashville (Tenn) Medical Department 1911 member of the Mississippi State Medical Association aged 65 died May 27 in a hospital at Jackson, of epithelioma of the mouth

Frank S Morris * McCool Junction Neb Medical College of Indiana Indianapolis 1887, for many years a member and at one time president of the board of education, aged 71, died May 1 of pneumonia and arteriosclerosis

Ronald Corbin Gyles, Siler City, N C Jefferson Medical College of Philadelphia 1917 served during the World War formerly health officer of Edgecombe County aged 43 died suddenly June 19 of coronary thrombosis

George Fred Lewis, Newton Mass Bellevue Hospital Medical College, New York 1886, formerly medical inspector

in the school department and later member of the school committee of New Bedford aged 77, died, June 15

Bayard Taylor Stevenson * Harvey Ill College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898 on the staff of the Ingalls Memorial Hospital aged 64 died, May 29

Charles Adam Laubach * Norristown Pa., Johns Hopkins University School of Medicine Baltimore 1913 aged 49 on the staff of the Norristown State Hospital where he died suddenly June 20 of coronary thrombosis

Robert Liston Irish, New York University and Bellevue Hospital Medical College, New York 1899 member of the Medical Society of the State of New York, aged 69 died June 6, in the Reconstruction Hospital

Daniel Thomas Sullivan, Mansfield Mass Bellevue Hospital Medical College, New York 1896 member of the Massachusetts Medical Society for many years school physician aged 66, died May 27, of myocarditis

Nellie Ettie Kurtz, Buffalo University of Buffalo School of Medicine, 1910 member of the Medical Society of the State of New York aged 52 died, June 20 of coronary thrombosis and diabetes mellitus

Roger Ralph Olsen * A Surg Lieut (j g) U S Navy, University of Illinois College of Medicine Chicago 1932 aged 30 hanged himself May 2 while a patient in a hospital at Washington, D C

John Thomson, Syracuse Neb Trinity Medical College Toronto Ont Canada, 1902, aged 66, died, May 23 in St Mary's Hospital, Nebraska City of pernicious anemia and chronic nephritis

Robert Hazlett Cummings Phillips * Trenton N J Jefferson Medical College of Philadelphia, 1896, on the staff of the Mercer Hospital, aged 71, died, May 10 of carcinoma of the rectum

O W Statham, Leesburg Ga Baltimore Medical College 1895, chairman of the county board of education aged 65 died May 19, in the Phoebe Putney Hospital Albany of Brill's typhus fever

Frederick Porter Hammond * New York College of Physicians and Surgeons Medical Department of Columbia College New York, 1889 aged 71 was killed June 3, by a trolley car

Foye R Troute * Denver Ohio State University College of Medicine 1917 served during the World War aged 46 died May 27 in Englewood Colo, of pulmonary tuberculosis

Melvin James Brown, Mars Hills Maine Baltimore Medical College 1896 member of the Maine Medical Association aged 83 died June 16, of arteriosclerotic heart disease

Gordon Edward Stanley, Hazelton, B C Canada University of Alberta Faculty of Medicine Edmonton 1934 on the staff of the Hazelton Hospital aged 31 died, May 24

David William Trout, Stockport Ohio Ohio Medical University Columbus 1901 member of the Ohio State Medical Association, aged 62 was found murdered, May 19

Frank Malcolm Child, Teaneck N J University of Vermont College of Medicine, Burlington, 1894 aged 67, died June 21 of chronic myocarditis and arteriosclerosis

Charles Rodman Townsend, Bridgeport Conn Albany (N Y) Medical College 1895 aged 64 died, May 27, of pulmonary tuberculosis and diabetes mellitus

Carlton A Smith, Oklahoma City, Kansas Medical College, Medical Department of Washburn College, Topeka 1903, also a druggist aged 65, died, May 3

Alois Anthony Thuner * Point Loma Calif Detroit Medical College 1879 member of the Michigan State Medical Society, aged 79 died May 24

Edward V Brown, Woodstock Ill, College of Physicians and Surgeons Keokuk, Iowa 1888 aged 81, died, June 4 of chronic myocarditis

Frank Woolford Finley, Williamsburg Ky University of Louisville Medical Department, 1892 aged 74, died June 11 of heart disease

Rufus Moos Wallace, Coryton Tenn, University of Louisville (Ky) Medical Department, 1887, aged 80, died, May 15

William Alvy Jones, Wildie Ky Louisville and Hospital Medical College 1908 aged 50 died June 7 of heart disease

Herbert Maw Caledon * Ont Canada Trinity Medical College Toronto 1897 died May 26

William Thomason Oliphant Ark (licensed in Arkansas in 1903), aged 73 died in Ala

MOONE'S EMERALD OIL

President of International Laboratories Fined as Shipper of Worthless Varicose Vein Treatment

The United States Department of Agriculture, in a release dated July 29, 1937, reporting terminations of criminal actions under the Federal Food and Drugs Act against some seventeen medicine manufacturers states that the largest fine was paid by Fred W Clements and the International Laboratories Inc, of Rochester, N Y, shippers of "Moone's Emerald Oil"

According to a commercial report, the officers of International Laboratories, Inc, consist of Frederick W Clements president, Miss Daisy E Clements, a sister, vice president and assistant treasurer, and a William Blamire, secretary and treasurer According to the same report, Clements is treasurer and manager of W H Buckley, Inc, manufacturers of proprietary medicines, Rochester, N Y He is also president and treasurer of E Griffith Hughes, Inc, of Rochester distributors of 'Kruschen Salts' (THE JOURNAL, Nov 21, 1931, p 1555), a one-third stockholder and official of the Scobell Chemical Company and a partner in the Johnstone Advertising & Sales Company

Clements was reported to have been at one time connected with the Moone Chemical Company of Rochester N Y which concern in 1916 was putting out an Emerald Oil for external use and claiming that the product was made famous through its power to exterminate pus germs and eliminate their poisons, destroy odors arising from ulcers gangrene cancers, relieve pain and assist Nature in restoring health to the parts" It was claimed to have been used extensively for pains, inflammations, swellings, neuralgias bites, bruises, burns, scalds, chilblains, pimples, sore throats, goiters, tubercular glands, boils, abscesses, carbuncles, ulcers, felons fissures, fistula, piles, ingrowing toe nails, gangrene, cancers, catarrhs and other discharges"

On July 12 1916, the United States attorney for the Western District of New York, acting on a report by the Secretary of Agriculture filed in the District Federal Court an information against the Moone Chemical Company, a corporation Rochester, N Y alleging shipment by the company, in violation of the Food and Drugs Act as amended, of a quantity of Emerald Oil that was misbranded It was alleged in substance in the information that the article was misbranded for the reason that the label bore false and fraudulent statements On Nov 20 1917 the defendant company entered a plea of guilty to the information and the court imposed a fine of \$25

Moone's Emerald Oil has been extensively advertised in various newspapers under such catch headings as 'Reduce Those Dangerous Swollen Veins,' 'How to Reduce Varicose Veins' 'Here's Speedy Relief From Bunions and Soft Corns' The nostrum has also been held out to the public as wonderful for ulcers old sores broken veins and troublesome cases of eczema In 1929 the International Laboratories was advocating Moone's Emerald Oil as a "marvelous antiseptic it destroys germs and poisons caused by germs, is such a remarkable healing agent that eczema barbers itch salt rheum and other inflammatory skin eruptions go in a few days For years it has been used for boils, ulcers abscesses and open sores that discharge and with the most perfect success" This remarkable remedy was claimed to be a Surgeon's Prescription and to have astonished physicians' There is no doubt that physicians would have been astonished to find varicose veins and eczema yielding to a green-colored mixture of mineral oil with camphor wintergreen and carbolic acid which the Food and Drug Administration reported the nostrum to contain

The painful experiences of two women who accepted the Moone's Emerald Oil advertising copy as trustworthy have

been reported to the Bureau of Investigation by the attending physicians In 1934 a New Jersey physician wrote

Recently I had a case of dermatitis venenata in a young woman who rubbed Moone's Emerald Oil into the skin of her feet The skin reaction was similar to that of poison ivy"

In 1935 a New York physician informed the Bureau

One of my patients, having read same [Moone's Emerald Oil advertisements], was thus induced to buy a bottle of this alleged cure and, after applying same in accordance with directions, she was obliged to go to bed because of the tremendous swelling in one of her legs and the appearance of an eruption on the areas where the oil was applied Subsequently both her legs became swollen, the skin became indurated, brawny in appearance and showed an extensive hemorrhagic eruption The hemorrhagic eruption was diffused over an area extending from the ankles up to the knees A few days later the entire body became involved There appeared a papular and macular eruption, some of which became confluent, forming large blotches Because of the itching and burning sensation the patient became very nervous, exhibiting chilly tremors, and had to be confined to bed for about ten days"

Although Clements, president of the firm, had pleaded not guilty to the government's charge in the recent prosecution that

the oil was neither germicidal nor a treatment for the disease conditions named in the labeling the government's allegation that the product was worthless for the conditions advocated was upheld by the jury finding of guilt

MISBRANDED 'PATENT MEDICINES'

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product (2) the name of the manufacturer, shipper or consigner (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Red Cross Pills—Red Cross Chemical Co Inc Fall River Mass Composition Essentially ferrous carbonate arsenic and manganese compounds potassium sulfate and plant extracts including tryphine and aloin For anemia kidney and bladder troubles impure blood Fraudulent therapeutic claims —[V J 24116 November 1935]

WTC Anti Pollen Salve—Corn Chemical Co Cleveland Tenn Composition Essentially aluminum chloride (21 per cent) in a mixture of petrolatum and wool fat For hay fever Fraudulent therapeutic claims —[V J 24092 November 1935]

Fink's Magic Oil—H G G Fink Laboratories Cincinnati Composition Essentially water alcohol (48 per cent) and small amount of essential oil including cinnamon wintergreen and saffron For malaria cholera morbus fever etc Fraudulent therapeutic claims —[V J 24106 November 1935]

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

AFTER CARE OF POLIOMYELITIS

To the Editor—I have been unable to find specific and detailed instructions in carrying out the care of paralysis following the acute attack of poliomyelitis. I will appreciate your sending me detailed information as to the best procedures to follow in a case of deltoid paralysis and paralysis of the flexor muscles of the foot. I should like information on these points: How to use the electric stimulation and galvanic currents in the muscle care; how often this should be done; how much active and passive motion is indicated; whether the arm should be kept elevated or allowed to remain in a sling; advisability of swimming and of how much benefit it is. Any further instructions you may have as to the care of these muscles will be appreciated.

M D Texas

ANSWER—The after care of paralysis resulting from acute poliomyelitis requires prolonged and intelligent supervision based on an accurate knowledge of the muscles involved. In the past, many diverse systems have been employed. Opinion now is more crystallized, variations being introduced only to favor paralyzed muscles. There have been several articles by competent authors in the past few years in the *American Journal of Physiotherapy* on the management in the recovery stage of this disease.

Orthopedic after-care begins the moment muscle weakness or paralysis is detected. At this time the extremities should be splinted in a position to relax most of the muscles. In the event of partial paralysis of a member, the position should favor the weakened muscles. The patient should remain in bed, resting on a firm mattress. In the upper extremity the arm should be kept abducted nearly to right angles on the chest, and in a neutral position as regards rotation at the shoulder, i. e., the forearm should be placed in the frontal plane. The position of the elbow depends on the relative strength of the flexors (biceps and brachioradialis) and the triceps extensor. If the latter is extremely weak, extension should be favored. The forearm should lack one third of full supination when extensive paralysis is present here. Special attention should be directed at an accurate analysis of wrist, thumb and hand palsy as much damage has been done in the past to the small muscles of the hand by lack of support. Usually the thumb should be splinted across the palm to relax the opponens pollicis and the adductor pollicis. Flexion at the metacarpophalangeal joints of about 30 degrees should be maintained unless a contraindication is present.

The pelvis should be prevented from sagging by suitable support in bed while the legs are maintained in from 10 to 15 degrees abduction at the hips, slight flexion at the knees, and with the feet at right angles to the legs, special attention being paid to the prevention of foot drop. In the event of focal weakness, as of the calf muscles, such groups should always be favored by relaxation. A strictly convalescent status without active care except general nursing and positional care should be maintained as long as any muscle tenderness remains. The extremities should be removed daily from support for bathing and slight daily passive motion at the major joints to prevent fixation from prolonged immobilization. Even then meticulous care should be taken to avoid rough handling. The physician should always be on the alert for contractures. These often develop rapidly but such deformities are preventable if vigorously combated. When tenderness is gone carefully planned graded active exercise is begun with the aid of water to provide buoyancy or a glazed or polished surface to reduce friction. There are no virtues inherent in either except that the use of water at a suitable temperature (90-95 F.) is most pleasing to the patient and enables exercise to be carried out with the minimum of effort. The types of exercises to be prescribed cannot be listed in so brief a space. Such textbooks as C. L. Lowman's *Technique of Underwater Gymnastics* (American Publications Inc. Los Angeles \$5) can be consulted. It is wise to employ an orthopedic surgeon at least in a consulting capacity to supervise the care of every case of poliomyelitis as the specific care to be given depends on the examination of muscles and judgment as to how much active exercise the patient should have each day. The slightest fatigue should be carefully avoided.

In a few weeks after the acute stage if paralysis remains only in an upper extremity the patient can be allowed out of bed with the paralyzed upper extremity supported on an air-

plane or platform splint. If the residual paralysis is in the lower extremity, extreme caution should be taken against allowing the patient to walk too soon. Braces should always be supplied when indicated. Recovery may be complete in a few weeks or months but in many instances it may extend over two or three years. The experienced orthopedic surgeon can usually give a reliable prognosis at the end of a year if paralysis remains at that time, provided he is in possession of data concerning progress during that year.

Answering specifically in the instances in which deltoid paralysis alone remained, such an extremity should be supported indefinitely on an airplane brace. Active exercises for this case should aim at strengthening any function detectable in the weak or paralyzed deltoid. These are best done with the patient in a recumbent position on a smooth table top or in a semirecumbent position in a moderate sized tank. Paralysis of the flexor muscles of the foot indicate that there is calf group and other paralyses in addition to the paralysis mentioned. An accurate estimation of the muscle strength should be made and the foot carefully splinted in the light of knowledge so gained. If the calf group is paralyzed with normal dorsal flexors, the foot is best supported in moderate equinus by a plaster splint with special attention that the arch is molded carefully and contraction of the plantar fascia avoided by some moderate dorsal pressure on the foot (as by web straps applied loosely). Exercises in this case can be easily given in a bath tub at home.

All electrical stimulation including galvanic and faradic applications to muscles or to nerves should be avoided. Rest in the optimal position and carefully graded active motion, protecting poorly functioning or paralyzed muscles from fatigue and stretching are the two important therapeutic agents used in the recovery phase of this disease. Passive motion should not be used except in minor degree to prevent fixation of joints. Swimming or other hydrotherapy should be used only as part of the program of active exercise and should be carefully supervised. In the two cases mentioned, a cautious start should probably be made at this time on a program of active exercise.

TRANSMISSION OF POISON IVY

To the Editor—The question has recently arisen in a compensation case as to whether or not poison ivy infection might be transmitted to a person exposed to the smoke from a fire in which poison ivy plants were being burned.

M D Washington D C

ANSWER—The active ingredient of all the *Rhus* species is toxicodendron, a phenolic oily resin contained in the sticky sap of the plant. While this is not volatile it may be conveyed for some distance on the soot of the smoke of a burning plant and produce typical lesions of poison ivy (Solimann Torald. *A Manual of Pharmacology and Its Application to Therapeutics and Toxicology*. Philadelphia W B Saunders Company 1936 p. 306).

LYMPHEDEMA OF LEG

To the Editor—I have under my care at present a woman aged 40 with refractory lymphedema of the left leg. The case is of ten years duration and despite all attempts to increase the lymphatic return the edema persists. It is probably of nonflarial origin the patient never having lived in a tropical zone. Southey's tubes have even been resorted to with only temporary relief the condition recurring shortly afterward. There is associated a mild parenchymatous nephritis with albuminuria and a few hyaline casts with a mild hypertension. There is no retention of nonprotein nitrogen however or increase in urea or creatinine. I am writing to inquire as to the possible efficacy of salyrgan or mercupurin in this condition and whether there are any reports in the literature as to the use of these drugs in conditions of lymph stasis or elephantiasis. Attempts to discover a possible source of obstruction to the lymphatic return have failed although abdominal exploration has not as yet been resorted to.

M D Illinois

ANSWER—There are two factors responsible for the swelling in lymphedema one of which is accumulation of unusual amounts of lymph in the tissues and the other of which is actual hyperplasia, or overgrowth of connective tissue. If the patient is put to bed and the extremity elevated in most cases of lymphedema marked reduction in the swelling occurs. This process is hurried occasionally by the use of diuretics such as salyrgan however the swelling will almost certainly recur if the patient becomes active again unless an adequate type of bandage is applied. The best kind of bandage is a pure rubber one 3 inches wide and 15 feet long. Ordinarily the bandage is applied over a hile stocking beginning by making two turns about the foot, two figure of eight turns about the ankle and progressing up the extremity to the knee. The toes and part of the heel are left exposed. The bandage should be removed and applied in the same manner each time as it becomes shriveled to the extremity on repeated use. If it is applied too tightly the toes become discolored cold and numb. If it is applied

too loosely, edema results. Patients soon become adept at bandaging their legs efficiently. The bandage should be removed at midday and reapplied over a dry stocking after the patient has rested for an hour. The same procedure is repeated at night if the patient is active. If he remains home he may remove the bandage and elevate the leg while sitting. Patients object to wearing the bandages because of the inconvenience in applying them repeatedly, the slight discomfort and their unsightly appearance. This is particularly true of women, who object to the appearance of the bandaged limb. Frequently a well fitting elastic stocking may be used for dress occasions and the use of the heavier rubber bandage may be reserved for ordinary activity. It is well to point out to women that the lymphedematous leg has an abnormal appearance which the bandage increases but little and to emphasize that uncontrolled edema almost invariably causes a gradual increase in the size of the limb. It is impossible to say how long the bandage should be worn, in some instances it must be used indefinitely; in others, improvement in circulation of the lymph may occur. Once every month or so the bandage can be left off for a day as a trial. If edema reappears, the support must be worn again.

In many instances in which there is marked increase in the size of the limb surgical treatment is beneficial. The modified Kondoleon operation decreases the size of the limb by removal of hyperplastic tissue and dilated lymph spaces. In a recent survey of sixty-four cases of lymphedema in which surgical treatment of this kind was used, there was improvement of varying degree in forty-one cases. The etiology, classification and treatment of lymphedema were considered in detail in the *Annals of Internal Medicine* 9:516 (Nov.) 1935.

TREATMENT OF ENDARTERITIS OBLITERANS

To the Editor—Will you please tell me what is considered the best treatment for endarteritis obliterans for a man 63 years of age? Would negative and positive pressure be indicated?

H. W. NYE, M.D. Osborne Kan.

ANSWER—The condition is better known as arteriosclerosis obliterans. The term endarteritis obliterans has been discarded for the condition characterized by arteriosclerosis with occlusion of the peripheral arteries since the term "endarteritis" indicates inflammation which is absent in most cases of arteriosclerosis. Since this condition is a chronic one treatment must be carried out over a long period. When the blood supply of the feet is greatly diminished or when there is ulceration or gangrene rest in bed is important since walking may cause injury to the tissues to which the blood supply has been impaired. Smoking should be discontinued since this causes vasoconstriction and contributes to the impairment of the circulation. Careful protection of the feet from injury of all kinds is important. The patient should do everything possible to avoid crushing and bruising the feet and toes, scratches, cuts, skin cracks, blisters, burns and frost bites. Only shoes that are comfortable and that do not bind or rub should be worn. Felt and wool lined shoes and soft woolen stockings should be worn in cold weather. Toenails should be cut straight across after soaking in warm water and should be carefully cleaned with orange-wood sticks. Corns, calluses and bunions should not be cut. If any chiropodist is done the chiropodist should be advised that the circulation is impaired. The removal of ingrown toenails and minor operations on the toes should be avoided as such procedures commonly precipitate gangrene. The feet should be washed carefully and gently at least every two or three days with mild soap and warm water, and 50 per cent alcohol should be applied after careful drying. If the skin of the feet is excessively dry and tends to crack or scale, hydrous wool fat and oil of theobroma may be used. Iodine, mercuriolate, sulfonaphthol phenol (carbolic acid), cresol preparations of soap-nated solution of cresol, carbolated petrolatum and similar preparations should not be applied to the feet since they may cause death of the tissue. Trichophytosis should be sought for and treated if present. However, ordinary preparations used in the treatment of this condition may be strong enough to cause ulceration. A safe method of treatment is to soak the feet in a 1:8000 solution of potassium permanganate. If infection is present in ulcers or gangrene the feet should be soaked in mild antiseptic solutions such as mild solutions of boric acid and preparations containing chlorine. A 10 per cent zinc peroxide salve or allantoin ointment may aid in cleaning up gangrenous areas. Epithelialization may be stimulated by a solution of thioglycerol. Postural exercises or treatment on the oscillating bed may help to develop collateral circulation; the former is carried out by lying on the back and elevating the feet to a vertical position until they become blanched and then sitting on the edge of the bed with the feet hanging down until

they become normal in color or excessively red. These procedures should be repeated a total of fifteen or twenty minutes three times daily. Contrast baths may likewise be of value. Two containers are used, each of which is large enough to immerse both feet to the midleg. In one is cold water (40 F) and in the other warm water (about 105 F). The feet are immersed for one minute alternately in the water of each container for periods of fifteen minutes two or three times daily. It is well to have a baker or a light cradle over the foot of the bed to see that the environmental temperature is elevated above that of the room but it should not exceed 105 F. Electric pads or hot water bottles applied directly to the skin should never be used. Intermittent pressure and suction may be of value and should be used at a minimum of two or three hours daily over a considerable period.

DIFFICULTY WITH SPEECH AND HEARING DEVICES

To the Editor—A boy now 6½ years of age is well developed and well nourished but is unable to talk and does not cooperate with his parents and attendants. The child was delivered normally without any history of obstetric injury, sat up at 7 months, walked at 14 months and had his first teeth at 7 months. From the beginning the parents noticed that he did not understand when he was addressed. However, during the first year of life he seemed to be able to utter a few noises as babies usually do. During the second year of life when the child was unable to learn how to talk and became hard to manage the parents became disturbed. However, they thought that he was a little backward in learning and they were not particularly greatly disturbed as the pediatrician who took care of the child told them that he was backward and that in time he would learn like the rest. About the third year when the child did not talk and he forgot the sounds that he had learned the parents again became alarmed and since have had him to many specialists and clinics. Two years ago he was taken to a well known clinic where a complete examination was done. I will repeat the most important observations. The hemoglobin was 14.1 Gm per hundred cubic centimeters, the red cell count 4,360,000, leukocytes 8,800. Tests for syphilis were negative. Roentgenograms of the head and chest and the Mantoux test were negative. Examination of the spinal fluid taken at the time of encephalography gave a negative Wassermann reaction. Nonne's test was negative. The protein content was 30 mg and the colloidal benzoin test was negative. The encephalograms disclosed nothing abnormal. An intelligence test could not be successfully made. The impression of the clinic was that the underlying aphasia must be a partial basis for the child's failure in development and that the striking disturbance in his behavior was partly reactive to his disorder of speech partly to his environment and possibly partly to disorder in its own name. At the advice of the clinic the child was placed in a well known school in Kansas which makes a specialty of treating cases of this kind. The child was kept there for almost a year without apparently any improvement in his speech. He is well developed, normal healthy and at times appears very intelligent. After the year was up the child was taken home because of lack of speech development and was placed in a school here in the city which specializes in the care of backward children. The child has made slight improvement since he has been at home and attending school. Recently he was taken to an ear, nose and throat specialist for examination and test for hearing. The examination disclosed that his sense of hearing is markedly impaired. Therefore the question comes up whether the child's condition is entirely due to faulty hearing. However, it seems rather strange that one of the best clinics in the country and a school that particularly specializes in the care of backward children had not informed us of this condition before. If we assume that the child's condition is due to hearing deficiency, what kind of a mechanical device would you recommend since there are so many on the market? Do you think that such a device will help his hearing and further his development?

L. M. SHAPIRO, M.D. Kansas City, Mo.

ANSWER—First of all it should be positively ascertained whether the child is so deaf that he cannot hear what people say. If so it may be only a case of ordinary deaf mutism. If not it is most likely a case of agencsis of the speech center since there is no reason to suspect birth injury or any brain disease that may have affected the speech center. We would not advise any mechanical device except after consultation with an otologist. The devices accepted by the Council on Physical Therapy are the acousticon, the audiphonic, the radio ear and the sonotone.

NEUROCIRCULATORY ASTHENIA

To the Editor—Please let me know if you have any information re a case of neuro-circulatory asthenia in a youth aged 16, weighing 172 pounds (78 kg) and 5 feet 9 inches (175 cm) in height. Schilling's count reveals 12 lymphocytes, 0.0 eosinophils, 1.0 myelocytes, 0.0 juveniles, 7.0 lymphocytes, segmented nuclei 8, lymphocytes 8 and large mononuclear 7. White blood cells number 8,500 and the red blood cells 5,320,000. The basal metabolism is 7 plus. The urine is normal with only a trace of albumin. The patient is hemophilic, he faints and passes out very easily.

GUSTAVE E. JACOBS, M.D. St. Louis

ANSWER—The diagnosis of neuro-circulatory asthenia is rather one. Grasping as a clue the statement that the patient faints and passes out very easily, it is assumed that this young man suffers from neuro-circulatory asthenia or the effort syndrome.

From the meager information given it would seem that the patient is in good physical condition. The Schilling count with its relative lymphopenia and rather high number of juvenile cells is not indicative in the presence of a normal total white count. There is no specific therapy for the effort syndrome. The treatment consists of good mental and physical management with the avoidance of drugs.

If the patient is a true hemophiliac it is something apart from the effort syndrome and should be considered as a separate problem. If he has merely a prolonged coagulation time it is probably unnecessary to do anything about it.

TONIC HEPATITIS AFTER DINITROPHENOL

To the Editor—Is there any helpful treatment for acutes resulting from degeneration of the liver brought on by the use of antifat treatment dinitrophenol? I have a patient 20 years of age who had an exploratory operation leading to the diagnosis of cancer. The surgeon prognosed her demise in six weeks which period now has extended to more than twice that. She has been tapped about every ten days and relieved of about 6 quarts of fluid each time.

M D Nebraska

ANSWER—Tonic hepatitis, or hepatic cirrhosis with portal decompensation, especially the latter, is an infrequent form of dinitrophenol poisoning. The former usually resolves when the drug is withdrawn, in addition to the use of a high carbohydrate, low fat diet and a daily saline aperient. Exclusive of syphilitic cirrhosis, there is no specific treatment for hepatic cirrhosis with ascites from whatever cause with the exception of the withdrawal of the particular hepatotoxin such as alcohol, arsenic or cinchophen. In this case the usual high carbohydrate, low fat and low salt regimen is indicated. Fluid should be restricted to 1000 cc daily for the time being. Satisfactory diuresis can be obtained by the use of salyrgan and potassium nitrate so that further paracentesis may be unnecessary. If there are no contraindications of a renal nature half of a 1 cc ampule of salyrgan is given intramuscularly as an initial dose. If there are no untoward effects the drug may be given in 1 cc doses thrice weekly. A maximum of 2 cc has been given at one time. As much as from 4 to 10 Gm of potassium nitrate may be administered daily. It is marketed in the form of enteric coated tablets of $7\frac{1}{2}$ grains (0.5 Gm) each. If adequate diuresis is not obtained by this procedure after a trial of from seven to ten days one must resort to occasional paracentesis and the administration of 10 per cent dextrose solution by phlebotomy. A tendency to acidosis may be combated by phlebotomy of 500 cc of 5 per cent sodium bicarbonate solution.

EFFECTS OF SODIUM PERBORATE ON TEETH AND GUMS

To the Editor—An article appearing in the May issue of *Hygiene* page 398 states that sodium perborate causes gingival manifestations such as pyorrhea. Is this so?

F D THOMPSON M D Chicago

ANSWER—The increased number of iatrogenic burns of the oral mucosae from the indiscriminate use of sodium perborate has led to serious misgivings concerning the use of drugs or of dentifrices containing it. The demand has been created largely no doubt by radio advertising.

The Council on Dental Therapeutics in its book *Accepted Dental Remedies* recognizes the use of sodium perborate for the treatment of Vincent's infection and related conditions. Such use is quite different from the ill advised use as a dentifrice or mouth wash as a supposed preventive for mouth diseases. The use of this drug as a mouth wash, a dentifrice, a bleach for the teeth or as an oral hygiene agent and as a preventive of 'pyorrhea' and trench mouth without individual attention by a qualified dentist or physician is against the public interest.

Sodium perborate was introduced about 1910 but until relatively recently its use was generally confined to sale on prescription. Few untoward incidents were noted which may be explained by its circumscribed use for relatively short periods and possibly to the directions for frequent rinsings of the mouth, a factor of some importance in the control of Vincent's infection. Following general advertising, particularly by the Vince Laboratories of New York, a number of cases of mouth burns were reported in the dental journals and by dentists.

When one considers the alkaline nature of the product and its widespread use, it is not surprising that undesired reactions began to be noted. Isadore Hirschfeld (*J Am Dental A* 21:776 [May] 1934) reported several cases of 'chemical burns,' hairy tongue and edema of the lips from the ill advised use of sodium perborate. Hirschfeld who has had a wide experience in the treatment of periodontal disease says: 'The patient was influenced by an advertisement to use a certain preparation of sodium perborate for inflamed gums. The lining of the cheeks

and lips became a heavy mass of necrotic tissue within a few days. After the perborate wash was discontinued, the burn healed rapidly. Although the solution used (1 tablespoon to the glass) is easily tolerated by the average person, clinical experience indicates that about 20 per cent of patients cannot use the drug stronger than a teaspoonful to three quarters of a glass of water without sustaining a burn of a greater or less degree. In view of these and other circumstances the Council on Dental Therapeutics will not accept dentifrices that contain sodium perborate.

These reactions in the mouth are not unlike reactions on the skin. Dr Leon Goldman (*The Skin Reactions of Infants and Children to Soaps in THE JOURNAL April 17 1937 p 1317*) notes that sodium perborate in a soap is the commonest eczematogenic agent. The patient with a contact dermatitis reacts more frequently to soap than the person with a normal skin.

It is not likely that sodium perborate will cause pyorrhea but it may cause gingival manifestations of the nature described. The danger rests in the possibility of secondary infection due to the inflammation of the tissues caused by the repeated application of an alkali-producing drug.

DIGITALIS THERAPY IN LACTATION

To the Editor—Is there any contraindication to digitalis therapy for a mother who is nursing her child?

M D Pennsylvania

ANSWER—Excretion of digitalis into the milk of the mother has not been demonstrated and is most improbable on theoretical grounds. It becomes fixed in all body tissues especially muscles and liver and is broken down into the digitalis genus and glucosides and excreted as such. It is found in edema fluid. There is no contraindication to administering digitalis to the nursing mother when there is a definite indication for its use, as in auricular fibrillation and passive congestion. As a factor of safety, it would be well to keep the baby under close observation.

LIQUID PETROLATUM IN PERITONEAL CAVITY

To the Editor—Will you please tell me what effect sterile liquid petrolatum will have if any when poured into the peritoneal cavity during operation? I have seen liquid petrolatum used for the purpose of preventing adhesions. Would it produce any inflammatory reaction in the peritoneum and might it actually produce adhesions? Could walled off globules of oil in the peritoneum produce a chronic irritation that might later result in malignant changes?

M D Georgia

ANSWER—When liquid petrolatum is placed in the peritoneal cavity it has a tendency to cause irritation. The pathologic picture is that of chylous-like fluid fatty necrosis of the omentum, and foreign body reaction with subsequent fibrosis. In patients in whom this procedure has been used, the liquid petrolatum did not prevent adhesions but caused them. The symptoms produced were those of vague, sometimes severe abdominal pains necessitating laparotomy and the excision of these fibrotic masses, this being especially true of some segments of the omentum.

It has been shown experimentally that irradiated petrolatum has no appreciable bactericidal effect on aerobic or anaerobic organisms in vitro.

Whether or not walled off fat globules of oil in the peritoneum might later result in malignant changes is problematic, but it does not seem likely.

SENILE VAGINITIS

To the Editor—Will you please outline the treatment for senile vaginitis?

JAMES P TAY M D Albany Ga

ANSWER—The origin of this condition is to be found in local nutritional or circulatory disturbances, atrophy of these parts resulting from the loss of ovarian function and advancing age. Local patches of raw surface appear where the vaginal epithelium has become denuded or cracked, and such surfaces readily adhere to one another.

The atrophic smoothness of the vagina and the narrowing of the introitus and canal are readily seen. The inflamed and also the denuded areas are visible, the granulating surfaces of the latter frequently oozing blood. Attempts at examination are painful and vaginal adhesions are easily detected.

Cancerous changes may be present and a positive diagnosis to the contrary cannot always be made. Segments of tissue should be removed for histologic examination when one is in doubt.

The prognosis is generally poor. Some alleviation of the difficulty is always possible but the process tends to be a progressive one especially if the patient is of advanced age.

For treatment, one may give douches once every day or two using compound powder of zinc sulfate (the pulvis antisepticus

of the National Formulary V), 10 Gm to 1,000 cc or $2\frac{1}{2}$ drachms to 1 quart of warm water. These are soothing and helpful.

Norman Miller recommends mildly antiseptic tampons (2 per cent mercurochrome with 10 per cent mild protein silver or 2 per cent phenolated glycerin) until the separated adhesions have healed and there is no longer any evidence of bleeding. The daily use of vaginal cones or capsules containing estrogen is helpful in certain instances.

DIPHTHERIA OF SKIN PRODUCING ABSCESES

To the Editor—A patient has multiple abscesses involving the muscles and fascia of the right thigh near the inguinal region which are deeply penetrating, are highly offensive and slough profusely. The condition proved to be of diphtheric origin and was cured by a single injection of 10,000 units of diphtheria antitoxin. There was and never had been any throat involvement. Kindly let me know whether similar cases are recorded and whether such conditions are frequent in any part of the body.

E. SHERIDAN ROANE, M.D., Richmond, Va.

ANSWER—Diphtheria of the skin, while unusual today, was not of extremely rare occurrence formerly. It has been observed often in connection with surgical conditions, sometimes following soon after such an operation as circumcision. Diphtheria of the foot has been noted after an operation for tendon transplantation and it has also occurred after abdominal operations. Under these conditions there is often marked sloughing of the tissues. Nose and throat cultures are likely to be negative. Before the days of active immunization, physicians working in contagious disease hospitals sometimes acquired diphtheria of the finger when performing an intubation. Trauma is usually a necessary factor for the diphtheritic infection.

Diphtheria may involve the skin of any portion of the body. It tends to run a more or less chronic course until treated with diphtheria antitoxin, which is generally strikingly effective. Constitutional symptoms may not be marked.

ALLERGY TO INSULIN

To the Editor—Can you help me out on a therapeutic problem? I have a patient who has diabetes mellitus passing a considerable amount of dextrose daily. She has had this condition for several years. I have recently started her on insulin a second time, the first time being about two years ago. She had had from six to eight injections of from 20 to 30 units twice daily, about three in the arm and five in the thigh. After each injection there is a localized reddened and slightly indurated area about the size of a silver dollar (38 mm) which itches intensely. This will last for two or three days. February 4 she was given an injection in one arm after a cessation of injections because of the local reactions for about three days. She ate about five minutes after the injections and about twenty minutes later I was called at which time she was extremely uncomfortable with intense itching over the entire body, especially the hands and the soles. The site of injection was reddened for an area of 2 or 3 inches radially from the point of injection. It was difficult for her to swallow, respiration was slightly difficult and the heart rate was from 130 to 140 beats per minute. One cc of epinephrine subcutaneously relieved this condition in about fifteen minutes. The reddened area—intense itching—lasted for about three or four days. I have been unable to explain this condition. The woman needs insulin. The brand used is insulin Lilly. Can you give me some help in this case? Is there another brand of insulin that would not give this reaction? What probably causes this reaction?

J. S. DUNCAN, M.D., Gary, Ind.

ANSWER—The patient is probably allergic to the traces of protein in the insulin that is being used. This insulin, as prepared for general distribution, is made from hog pancreas. The same firm can supply insulin derived from beef pancreas which the patient will probably be able to take without trouble.

DERMATITIS HERPETIFORMIS

To the Editor—A patient of mine has suffered from dermatitis herpetiformis for some years. He has taken from 8 to 30 drops of solution of potassium arsenite daily for three years. At present he is taking 8 drops daily. The skin of the entire trunk, legs and arms but not the face is heavily pigmented almost black. He has also a large keratosis in the scar of a pressure sore on one heel. The scar was caused by a cast applied to heal a fracture two years ago but the scar has recently built up to a thickness of three eighths inch and is rough and jagged. The patient is so terrified because of the itching of the dermatitis herpetiformis that nothing will persuade him to discontinue the arsenic even for a few weeks. He claims that the dermatitis herpetiformis appears if he decreases the dose of Fowler's solution below 8 drops daily. Is the patient likely to cause any permanent damage by the prolonged ingestion of arsenic? If so could you suggest another remedy for the dermatitis herpetiformis?

M.D., Ontario

ANSWER—The patient is already suffering from a probably permanent injury in his pigmentation. Quinine autohemotherapy and prolonged neutral baths are remedies worthy of being tried in the case.

LOCOMOTOR ATAXIA WITH RECTOGENITAL CRISES

To the Editor—A man aged 51 has locomotor ataxia with crisis of the rectogenital organs. He contracted syphilis about sixteen years ago. He had at that time only three injections of arsphenamine for the secondary eruptions. Then there was a period of quiescence of symptoms of the syphilis for ten years. Thereafter about six years passed the patient began to notice some difficulty in micturition and bowel movements. Meanwhile there were lightning pains. Then two years later there were staggering gait and a sensation of thickness under the feet. In the year next to those two there came the rectogenital crisis, quite extremely painful suffering. With regard to the crisis the patient said that it acquired the spasmodic contractions of the anal orifice and rectal tenesmus in the rectum and at the same time there was a drawn feeling of the penis so that he had to hold and rub it with a hand against the pubis or he must make a hurried walk in order to counter it. Spasmodic acts of the muscles. There were also tossings of the lower half of the body during the spasms. This fit was more severe following each defecation and urination especially after a sleep. The spasms lasted about an hour from two to three hours later becoming quiet. Before the crisis appeared the patient felt as if something were running from the lumbar region down to the anus behind and penis in front hence the tragedy. Sometimes this feeling traveled upward effecting an oppressive sensation in the chest and thus making the crisis less severe. Moreover a performance of strokings applied to the sacral region might also ease the patient a little from the spasms. There were desires of frequent micturition at the height of the spasmodic contractions. He slept very badly. He had to get up at night by the crisis following the longing for voiding urine when he was going to fall into sleep. The bowels were constipated and spastic in manner. The crisis was suppressed by the smoking of some opium whenever it occurred but was greatly exaggerated by the sudden total withdrawal of the drug in the autumn before last. Since then this exaggeration of spasms has no longer been arrested by opium. The patient consulted me last spring for his chief complaint the rectogenital crisis. On examination he was slightly undernourished. There was gingivitis. He could not stand well quietly there were some swingings of the body. The pupils were contracted unequal in size and not accommodated to light. The tendon reflexes of the knee and ankle joints were also lost. There were hyperesthesia and hypesthesia on both legs. The skin of the lower half of the body was somewhat roughened and scaly and itchings of that part were constant. There were numerous petechial spots on a forearm being produced by the application of a hemomanometer. The heart was much hypertrophied. There were to and fro murmurs in the aortic region. The blood pressure was 186 systolic and 28 diastolic. The pulse was 20-30 beats more than normal. The Wassermann reaction was strongly positive. I treated the patient first with acetylarsan and then changed to solu salvarsan of 3 cc each of two doses and another of 4 cc which was reacted to the next day by polyneuritis and increased tendency to rectogenital spasms. After a rest of three weeks I gave thiobismol and iodomaisin. Now I have again changed to iodine pills to mirror and bismuth to neoarsphenamine started at 0.05 Gm strength. They are injected alternately in each week. Further I have prescribed a combined use of vitamin B for the degenerated nerves of the spinal cord. It was injected daily except on the days of neoarsphenamine and iodine. While having been treated so long (about ten months in the course) there are indeed at present some improvements of the skin of the lower extremities being smooth to touch and relieved of itchings. Besides as combined with the vitamin injections, thirty in number the spasms of the rectogenital organs are comparatively not so severe following each urinary and fecal discharge as it formerly did without the vitamin indications. The appetite is rather good and to be sweet. The sleep is somewhat sounder than ever before. The systolic blood pressure is something about 160 but the diastolic pressure is still 28. The pulse diminishes its frequency to normal in quiet times and is yet around 80 during the fit of muscular contractions of the anus and penis. The bowel discharges were easily made every day for two months at a time not long before the present but recently they became spastic again. The serum test is still positive. Kindly advise me how to manage the case particularly to control the crisis in order to do away wholly with the patient's sufferings whereby to spare the damaged heart. What is your idea about the vitamin B to the degenerated heart?

SUEN CHIA SHAN, M.D., Tientsin, China

ANSWER—The treatment of cases of the type described is often discouraging. On the whole, rectal crises respond better to treatment than do gastric crises and continuation of intensive antisyphilitic therapy, is indicated. A number of the drugs mentioned are unfamiliar. Of the drugs used in this country the best results on the whole are obtained with the intensive use of arsphenamine, giving in the neighborhood of thirty six to forty injections in four courses, in combination with double the usual number of injections of a bismuth compound. If the serologic responses of the spinal fluid are strongly positive and associated with a high cell count intraspinal therapy may be tried.

The results with fever therapy, on the whole are not encouraging and the general condition of the patient would hardly permit cordotomy. If a deficiency of vitamin B was present as seems probable from the response obtained with its administration it is possible that the nerves governing heart action were included in the deficiency. It would seem advisable to continue this method of therapy. For relief of the crises themselves the administration of chloral 0.6 Gm and bromides 0.6 Gm given with 30 cc of olive oil instilled into the rectum may give relief.

UNDESCENDED TESTES UNDER FIVE YEARS OLD

To the Editor—Have there been any investigations of the use of gonadotropic substance in the treatment of undescended testes in patients under 5 years of age? All reports I have seen so far have been on older patients. Would there be any risk involved in treating a patient 3 years old who has unilateral cryptorchidism but who is apparently normal other wise?

M D Connecticut

ANSWER—The use of gonadotropic substance in the treatment of undescended testes is not advised at such an early age as 5 years. In many instances patients with unilateral cryptorchidism will undergo a spontaneous cure without any treatment. There is no contraindication to the use of a gonadotropic substance at an early age, but experience has taught that it is better to postpone active medication for a period, as many of these cases will be relieved without treatment.

EFFECTS OF CALCIUM AND VITAMIN D ON
CARIES DURING PREGNANCY

To the Editor—A reply in *Queries and Minor Notes* in THE JOURNAL May 22 would imply that the administration of an abundance of calcium and vitamin D might prevent dental caries during pregnancy. It is unfortunate that the answer gives certain references to articles that leave the impression that an abundance of calcium and vitamin D is useful in the treatment of this disease. It unfortunately overlooks the circumstance that the greatest progress in the control of dental caries has been made not by such diets but by the operative procedures which dentists have long practiced, i. e. removal of the carious areas and treatment and restoration by conservative methods. Unfortunately treatment today is largely arrestive not preventive.

The thesis that the administration of calcium and vitamin D for prophylaxis against dental caries is appealing but the evidence to support it has been disappointing. There can be no quarrel with the general position that a diet ample in calcium and vitamin D is useful to the mother during pregnancy. The effect this has on the carious process of a child or mother is still an open subject. This subject was amply covered in a review of the problem by the Council on Dental Therapeutics in a report entitled *Calcium and Phosphorus Compounds in Dentistry* (J Am Dent A 22 139 [Jan] 1936). That article was the basis of an editorial review in THE JOURNAL May 8 page 1655.

The evidence available does not support the view expressed in the dictum "for every child a tooth, as far as pregnancy is concerned." Mull and Kinney (Am J Obst & Gynec 27 679 [May] 1934) studied the blood and teeth of a large series of pregnant women and concluded:

There is no appreciable change in the teeth of women during pregnancy or the first weeks of lactation other than that which would probably occur in a similar group of nonpregnant women during the same period of time. The levels of the calcium and the inorganic phosphorus of the serum of the pregnant women bear no direct relation to the condition of her teeth. There is critical clinical confirmation of these observations.

Hunscher (J Biol Chem 86 55 [March] 1930) found that negative calcium and phosphorus balances were found in early lactation in spite of large intakes of these elements, but, in late lactation when less milk was secreted both calcium and phosphorus were stored in the maternal body. Macy (ibid p 59) found in addition that daily feeding of cod liver oil and yeast during the highest period of milk flow resulted in greater calcium and phosphorus utilization. No notation is made in that article concerning the effect on the teeth.

The foregoing is interesting nevertheless in pointing out that not calcium or phosphorus alone but vitamin D is important. This would appear to warrant the conclusion that not only the absolute amounts of calcium and phosphorus but those materials on which they are dependent for fixation are important. There is other evidence which bears on this point but which need not be cited here.

If a pregnant woman is to take calcium and cod liver oil during pregnancy it should be taken with the understanding that it is more important for purposes of general hygiene and good health barring other complications during this period than for the effect on the teeth of the mother and milk as a source of calcium in preference to tablets or powders is to be preferred for obvious reasons.

If caries occurs during that period one should avail oneself of the benefit of operative dentistry. This as far as available information goes is the surest means of avoiding the further ingress of dental decay.

SAMUEL M GORDON Chicago

Secretary, Council on Dental Therapeutics

NEUROLOGIC SYMPTOMS DUE TO TRAUMA OR
ARTERIOSCLEROSIS

To the Editor—In your reply to Dr E L Finley of Oneida N Y regarding neurologic symptoms due to trauma or arteriosclerosis (THE JOURNAL July 24 p 298) you state that there is no evidence to show that an accident could have brought about the neurologic syndrome mentioned. Pain in the back, loss of strength and difficulty in getting about. In view of type of injury 200 pounds punning him why could he not have sustained a fracture of the vertebral column or injury with possible rupture of the intervertebral disk? While the patient was lying flat in bed he had no symptoms but the moment the casts were removed from both lower extremities and he was permitted to assume the erect position his syndromes began to appear. Does this not suggest injury to the spine that was perhaps previously overlooked? Unless there is proof that this injury was ruled out entirely it should be kept in mind. Although the loss of speech cannot be accounted for the pain in the back is too important a single symptom from the point of view of trauma to be completely dismissed.

Arkansas June Examination

Dr L J Kosminsky secretary, State Medical Board of the Arkansas Medical Society reports the written examination held at Little Rock June 17-18 1937. The examination covered 12 subjects and included 100 questions. An average of 75 per cent was required to pass. Forty four candidates were examined, all of whom passed. The following schools were represented:

School	PASSED								Year Grad	Per Cent
University of Arkansas School of Medicine									(1937)	78.8
79.4	79.8	80.2	80.3	80.3	80.6	80.6	80.7	81.2

Nebraska June Examination

Mrs Clark Perkins director, Bureau of Examining Boards reports the medical examination held at Omaha June 8-9 1937. The examination covered 10 subjects and included 92 questions. An average of 75 per cent was required to pass. Seventy eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Creghton University School of Medicine (1936 3)		(1937 11)	14
University of Nebraska College of Medicine (1936)		(1935)	64

Book Notices

Medical Uses of Radium. Summary of Reports from Research Centres for 1935. Medical Research Council Special Report Series No. 216. Paper Price 1s. Pp. 38 with 9 illustrations. London: His Majesty's Stationery Office, 1936.

As formerly this report reviews the research done during the year with radium and radon distributed by the Medical Research Council to selected centers in Great Britain and Ireland. In the experimental section the investigations on cellular action conducted in Strangeways research laboratory in Cambridge are reported under three headings: biologic response as a function of the intensity of radiation (Spear and Hughes), the effect of gamma radiation on cell division in the tadpole (Gluecksmann and Spear) and the mode of action of radiation (Lea, Haines and Coulson). In the St. John Clinic and Institute of Physical Medicine, Taylor has made some studies aimed at the determination of the effect of combining low frequency (so-called ultra short) waves with high frequency oscillations (gamma rays) on tumors of the rat. These examinations showed that the sensitivity of the Jensen rat sarcoma and the Walker carcinoma to radium radiation was not affected by the ultra short waves. At the Imperial College of Science and Technology the measurements during the last year of the effect of temperature of a neutron gas on the absorption of a neutron into silver nuclei has been extended by Moon and Tillman to a number of other elements. From the Mount Vernon Hospital and Radium Institute, Mottram reported on the variations in sensitivity of the cell to radiation in relation to mitosis and on mesoblastic tumors produced in fowls by exposure to radium.

Interesting experiments from the clinical point of view have been performed at the Holt Radium Institute in Manchester by Ham. He treated skin epitheliomas and rodent ulcers with the radium mold, using different distribution in time of the same total dose. In one group of patients he applied the radiation treatment on the first and third days and so on, that is, at intervals of forty-eight hours. In another group he applied the same amount of treatment on the first and fourth days and so on, that is, at intervals of seventy-two hours. In a third group he applied the same total dose at intervals of one week, that is, half of the treatment on the first day and the other half on the seventh day. The results disclosed the fact that irradiating with the split dose as described definitely reduces the skin tolerance compared to the same dose applied with continuous treatment over seven days. The skin reactions were much more pronounced with the split dosage which was most intense when only two treatments were applied, on the first and on the seventh day.

John Ross of the Royal Free Hospital performed experiments in rabbits with the purpose of inducing malignant tumors by implantation of radium tubes, based on an accident in clinical experience when a radium needle used in the treatment of cancer of the breast was lost. This needle became embedded in the intraventricular septum of the heart, and death occurred three years later from a gradual heart failure. At necropsy a malignant hemangioma was found in the liver immediately underlying the needle. In the experiments on rabbits the author could produce five sarcomatous tumors and two squamous cell carcinomas around the embedded radium tubes.

The clinical section of this report is grouped round the new modes of technique for the treatment of cancer in various parts of the body and the statistical records of the results of treatment over a period of years. Cancer of the breast, corpus and cervix uteri, mouth, nasopharynx, larynx, esophagus and rectum are considered. For cancer of the breast no decidedly new method has been used, radiation being reserved for the inoperable lesions or in combination with surgery. In cancer of the cervix the Marie Curie Hospital reports a five year survival rate out of all treated cases of 36.79 per cent (170/462) for patients treated between 1925 and 1930. A slight improvement is noted for those treated during the later years, giving a five year survival rate of 42.6 per cent for patients treated in 1930 against 30 per cent for those treated in 1925 and 1926. The results of treatment of cancer obtained by the different centers are tabulated. No essentially new method of approach is reported in the treatment of cancer of the rectum.

Live Long and Be Happy. How to Prolong Your Life and Enjoy It. By Jewell F. Barker, M.D., Visiting Physician, Johns Hopkins Hospital. Baltimore: Cloth. Price \$2. Pp. 224. New York & London: D. Appleton Century Company, Incorporated, 1936.

This book, which, according to the author, is intended for the "intelligent laymen who wish to prolong their individual lives and for general practitioners of medicine who will advise such laymen as to the best methods," attempts with this declaration an almost impossible task. The material is given according to a well considered outline. The author begins with a discussion on the desire for long life and continues by pointing out the changing duration of human life and on what such longevity depends. He discusses heredity, environment, personal habits and occupations in their relationships to longevity. Following this he points out how life may be prolonged through the prevention and adequate treatment of infectious diseases and diseases of the heart and blood vessels, digestive apparatus, excretory organs and locomotor system. The final chapters deal with the prevention of nervous and mental diseases, as well as diseases of metabolism and the endocrine system that may shorten life. Such a table of contents will intrigue the lay reader as well as the physician, who, after all, is a teacher of health as well as a healer.

After the third chapter, the book attempts to carry out its promise made in the preface and to give information to lay reader and physician alike. The book from here on becomes a semitechnical handbook that serves neither of its avowed masters well. For the layman, to achieve long life and happiness becomes difficult when, for example, the various definitions given for diseases of the respiratory tract are too brief to be informative. The disease condition bronchiectasis is dealt with in seven lines. Pulmonary emphysema is probably of academic interest to most laymen. The difference between catarrhal and diphtheritic laryngitis is of interest to the layman and deserves far more space than the few lines given to it, which mention that during the latter condition "an intubation tube may have to be inserted." For the physician, the short definitions in this chapter are superfluous, since they give him no new knowledge and only an extremely meager review of well known facts.

Another objectionable feature is the attempts of the author to give references to medical literature. Such references to medical journals are necessary when writing for a physician, but the layman usually experiences great difficulty in obtaining the technical journals. Then, too, such journals are never written in language easy for the layman to understand. Examples of such references are found where the author states in discussing pneumonia: "Experiences of F. G. Blake and his associates in New Haven indicate that artificial pneumothorax induced soon after onset is invaluable. . . . seventy-two hours after onset", "abnormal movements like those of myoclonia", "Isaac advises the use of acetyl-beta-methylcholine."

Dietetics Simplified. The Use of Foods in Health and Disease. By L. Jean Bogert, Ph.D., Consultant in Nutrition, Delmonico Institute, New York City. With Laboratory Section. By Vame T. Porter, M.A., Head of Home Economics and Nutrition, Department of Public Welfare, University of Illinois. Cloth. Price \$3. Pp. 637 with 75 illustrations. New York: Macmillan Company, 1937.

The authors attempt the difficult role of providing a simply written yet thoroughly scientific text on dietetics to be of service to students in home economics courses, to hospital dietitians, to nurses and medical students, as well as to physicians who desire to educate their patients and to "intelligent housewives." It appears manifestly impossible to teach at one and the same time such a heterogeneous group of readers. This is particularly true when a knowledge of chemistry is one of the backbones of nutrition. In an effort to simplify the subject of dietetics the authors have allowed factual errors to enter, e.g., "the food carbohydrates consist of starch, double sugars and single or simple sugars," and a large number of like misstatements. It is assumed that the authors intend to be practical. Why then select dry gelatin as an illustration of the calculation of the caloric content of protein? What would one want with 100 Gm of dry gelatin? All the gelatin one could eat at a sitting amounts to 5 Gm. Furthermore it is stated on page 25 that gelatin is 100 per cent protein whereas the table on page 604 reveals that it is 91.4 per cent.

protein Egg white is also given as 100 per cent protein, despite analyses to the contrary. It is realized that these are used merely as illustrative material in the text but they show poor choice and correlation. On page 30 among foods listed as rich in sugar are cocoa and chocolate, which in the unsweetened state are not edible as such. On page 27 the following is to be found: "An animal starch called glycogen also exists but is found in appreciable quantities only in such foods as liver, oysters and other shell-fish." It is feared that this statement is derived from the fact that in the majority of analyses of meat, mention of the carbohydrate content is omitted and therefore it is erroneously assumed that meat is starch free. The contrary is the case. In the carbohydrate analyses of muscle it has been conceded that the carbohydrate is in the form of glycogen and in a great number of meat items it is present in more than appreciable quantities. On page 31 fish is listed as being a food rich in fat, i. e., between 10 and 25 per cent. In the most recent analyses of all the fishes the only items among all the fishes which in the raw state meet this qualification are bloater, butterfish, finnan haddie, mackerel, salmon and swordfish. It is surprising to note on page 31 that a diet high in starch "may be a predisposing factor in arthritis." Part II, on diet in normal conditions encompassing menu building, adequate diets for normal adults and food for children and elderly people, is recommended. It appears that these angles of dietetics are studiously avoided in the average textbook. However, one may take exception to a protein intake of 50 Gm of protein daily as being ample after 60 years of age. The volume cannot be recommended for detailed accuracy, but in a newer, corrected edition it should find a place in the teaching of elementary dietetics.

Les régimes chez l'enfant Par L. Rabonnelle, médecin de l'Hôpital Saint Louis. Paper. Price 75 francs. Pp 607. Paris: Masson & Cie 1936.

The book is divided into three main parts. The first part deals with general physiologic aspects of nutrition and with the phases more closely associated with the nutrition of children. In this part the importance of certain amino acids for life, maintenance and growth is given due consideration. Methionine, it may be mentioned, should be included among the important sulfur-containing amino acids, and glutathione is given as a dipeptide instead of as a tripeptide. An excellent feature of the book is the discussion of the vitamins. In the chapter on minerals, magnesium, with its specific role in the production of lactic acid under certain conditions, may perhaps deserve a little more attention. Another praiseworthy section is the one devoted to the interrelation of various nutritional elements—proteins, fats and carbohydrates, as well as salts, vitamins and water.

The second main part concerns the dietary management of the normal and the sick infant. The advantages of maternal breast feeding are stressed. A few quotations from general and medical literature are given to demonstrate the advantages of breast feeding for the mother's health and beauty. The efforts at stimulating breast feeding in France are noted. In the chapter on the nutrition of sick infants various diets are given, starting with a water diet. Diets based on buttermilk and other acid milks, on dried and condensed milk and on other foods, such as soya meal, are included. The preparation, composition, indications and contraindications are described. Among the humanized milk mixtures synthetic adapted milk might have been included. The milk of asses is given more prominence than is usual, and it is emphasized that the milk spenders should be fed on dry fodder. Protein milk (Finkelsstein) is dismissed in a manner indicating little experience with it. Fruits and vegetables are not neglected. Under special headings, mainly with reference to dietetic management, are discussed the ailments of the infant, such as anemia, anorexia, nervosa, arthritis, with its two main subdivisions of hepatic insufficiency and toxemia, which is a rather problematic entity, and avitaminosis, deficiencies of protein, carbohydrate, fat, minerals and water. Cholera infantum, constipation, congenital debility, various forms of diarrhea and dyspepsia, atresia, eczema and intestinal infantilism (celiac disease) are also discussed. Parenteral infections are considered as well as gastric, hepatic and pancreatic insufficiency, alimentary allergy, prematurity, rachitism, overfeeding and habitual vomiting. In

the rather uneven chapters on these subjects the author often gives a short paragraph of his personal opinions.

The dietary regimen of children from 2 to 15 years of age forms the subject of the third main division, to which thirty-three pages are devoted. In the first part, dietary regimens of normal children are given, and in the second part those of sick children, under the main headings of diseases of the circulation, skin, digestion, nervous system and respiratory tract, infections of the urinary tract and diseases of nutrition including obesity and diabetes, and diet after operation. The second subdivision of the third part is a rather ambitious undertaking, the ambition is perhaps not realizable in such a short compass, and as is to be expected, the section is not free from omissions and other faults.

If one compares the facts in the book about the physiologic aspects of nutrition with the nutrition of patients it becomes evident that there still exists a considerable cleft, the bridging of which will need much further effort. The book has many highly commendable and attractive features.

Manual of Biological Assaying By James C. Munch, B.S., M.S., Ph.D., Professor of Pharmacology and Bioassays, Temple University School of Pharmacy. Paper. Price \$2. Pp 181 with 22 illustrations. Philadelphia: London: C. Montreal: J. B. Lippincott Company 1937.

This brief compendium of methods used in the bio-assay of drugs, although intended for a wider audience, will be found useful chiefly by the student. In addition to concise instructions on the performance of many tests, blank tables and pages are included in profusion for recording experimental data. Among the materials for the bio assay of which directions are given are aconite, anthelmintics, arsenphenamines, biologic products, cannabis, digitalis, epinephrine, ergot, insecticides, insulin, local anesthetics, morphine, parathyroid extract, thyroid, sex hormones and vitamins. For some of these (e.g., estrogens and androgens) actual working details are insufficient for others they appear to be satisfactory. Absence of pagination in the major portion of the book makes reference unnecessarily difficult.

Die Herz und Gefässkrankheiten Von Professor Dr. Walter Frey, Direktor der medizinischen Universitätsklinik Bern. Paper. Price 29 marks. Pp 342 with 67 illustrations. Berlin: Julius Springer 1936.

The author has written a scholarly treatise on diseases of the heart and blood vessels. Instead of cataloging the known facts of the clinical aspects for ready reference he has presented a logically developed summary, correlating the pertinent facts and theories concerning this subject. The material consequently, is developed on an etiologic basis, and the morphologic and physiologic data are brought in where they apply. The same applies to symptoms, signs, diagnosis, prognosis and treatment. Little is said about the distribution of diseases as usually handled when discussing etiology, and this is a favorable aspect of the book. The first section discusses the embryologic origin and development of the heart and blood vessels. The second section discusses in turn the congenital malformations, the normal and abnormal development of the cardiovascular system with age, and the involution of the heart and blood vessels with senility. The third section of the book deals with the sclerotic process. This is subdivided into sclerosis of the heart, the arteries and the veins. This section is properly the longest in the book, and coronary sclerosis receives the greatest consideration. The next section deals with damage of bacterial and toxic origin. There is a discussion in general terms, followed by the action of various bacteria and toxins on the heart arteries and veins. In the final section damage caused by the endocrine system and the vegetative nervous system on the heart and vascular systems is presented. Glandular dysfunction as well as the various neuroses is considered in this section. The organization of this book is different from most dealing with this subject and is an improvement from the point of view of the development of the subject scientifically. While exception may be taken to many of the statements the reader of experience will find a great deal of factual data and theoretical argument which will be stimulating. He will be impressed by the fact that the subject dealt with is not morphology, physiology, bacteriology, pathology or the practice of medicine but in the truest sense is medical science. The book shows beautifully how the conglomeration of facts gathered

from many fields can give rise to a new science. The author demonstrates his familiarity with the international literature. He has kept abreast of the developments of his field and has introduced few personal biases. This book is recommended in the highest terms for the serious student of diseases of the heart and blood vessels.

The Dosage of Antitoxin in Diphtheria. Report of Departmental Committee Appointed by the County Medical Officer of Health and School Medical Officer. London County Council No. 3225. Paper. Price 6d. Pp. 14. London: P. S. King & Son Limited, 1936.

This report is "an attempt to establish criteria for the guidance of the medical officers of the Council's hospitals." It takes up the matter of diphtheria toxin, its tissue combination, and the aim of antitoxin treatment. Emphasis is laid on the time factor and it is insisted that "every hour, every minute of delay—and this is not a figure of speech—is damaging. If the amount of toxin is near the lethal dose, life itself is at stake" (Schick). Intravenous administration is designated as the ideal route when rapidity of action is necessary, but not all cases are recommended for this technique. The intramuscular route is recommended when speedy absorption is less urgent. A single dose is recommended rather than repeated doses. Serum reactions and other unusual effects are briefly but adequately discussed and desensitization is outlined. There is an excellent brief outline of the clinical manifestations of diphtheria. The booklet is a useful summary of the best current knowledge with relation to the early and adequate administration of antitoxin in the treatment of diphtheria.

The Diagnosis and Treatment of Diseases of the Stomach and Intestines. By William Fitch Cheney, B.L., M.D., Henry A. Christian, M.D., Sc.D., LL.D., General Editor of the Series (Reprinted from Oxford Monographs on Diagnosis and Treatment). Cloth. Price \$5.50. Pp. 378. New York: Oxford University Press, 1936.

As a large territory is encompassed in a comparatively small volume, consideration of the various diseases is necessarily brief. In the main, only the commoner, clinically most important, diseases are discussed. There are not many statements with which authorities would disagree. For example, the remark that the great majority of ulcers of the stomach are situated at the pyloric end is debatable. Most chronic benign ulcers are situated at the pars media and lesser curvature as a matter of fact, although the pyloric antrum is a commoner site of gastric carcinoma and carcinomatous ulcers. In the article on chronic gastritis, it is obvious that only the superficial catarrhal, or probably the atrophic, variety is described. The statement that gastric analysis alone supplies the evidence on which a diagnosis of chronic gastritis depends is seriously open to question. Of the various benign tumors, only gastric polyps are considered. The chapter on reflex disturbances of gastric function, especially that portion dealing with appendiceal dyspepsia, is admirably done. Treatment is given ample and sane consideration. The volume has two noteworthy features: (1) a gastro-enterologic point of view of the clinician of the older school and (2) a fine literary quality characterized by simplicity of diction and construction which every medical writer might emulate. Regardless of minor shortcomings, the book can be read with pleasure and profit by practitioner and specialist alike.

Studies and Investigations into the Corpus Luteum Hormone. By Kai Portman. Paper. Pp. 124 with 8 illustrations. Copenhagen: Levin & Munksgaard, 1935.

The author presents here a summary of investigative work performed by him at the University of Copenhagen from 1931 to 1933, with brief discussions of the literature. This work, of course, was completed before crystalline progesterone was isolated and prepared by pseudosynthesis in 1934 and therefore deals with potent but not completely purified preparations. The work described should be of interest both to investigators and to clinicians, representing extensive experiments in animals as well as a series of clinical cases. Much of this is in agreement with reports that have appeared in recent medical literature. An interesting observation made by the author is that by feeding massive doses of progestin to rabbits a slight effect on the uterine mucosa could be obtained. It requires more than fifty times as much by mouth as by injection to produce a detectable effect in the rabbit, owing to destruction of the active principle

by the digestive juices. Favorable results in the treatment of forty patients with menorrhagia, symptoms of the menopause or threatened abortion are described.

L'infection bacillaire et la tuberculose chez l'homme et chez les animaux. Étude biologique et expérimentale. Vaccination préventive. Par A. Calmette. Fourth edition revised by A. Boquet and L. Nègre. Cloth. Price 175 francs. Pp. 1024 with 69 illustrations. Paris: Masson & Co., 1936.

The advances in the knowledge of the tubercle bacillus and of tuberculosis since the previous edition was published nine years ago have been incorporated into the present edition without any change in Calmette's original plan. The book deals primarily with the fundamental—strictly scientific as distinguished from the social—problems of tuberculosis. There are four parts: the bacillus of tuberculosis, the anatomic form of tuberculous infection, its localization and routes of entrance (404 pages), experimental tuberculosis and tuberculosis of animals, the defense of the body against tuberculosis and the use of the reactions of defense in diagnosis, natural immunity and processes of immunization against tuberculosis. There are twenty-four fine plates in colors and many black and white illustrations. Calmette's great book remains a standard, comprehensive French work on the bacteriology, morphology and immunology of tuberculosis.

Recent Advances in Endocrinology. By A. T. Cameron, M.A., D.Sc., F.R.C. Professor of Biochemistry, Faculty of Medicine, University of Manitoba. Third edition. Cloth. Price \$5. Pp. 458 with 60 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

This is the third edition of this member of the Recent Advances Series in a little more than three years. The new volume has been enlarged by the addition of about fifty pages containing new material. In general the work has been improved over previous editions (reviewed in *THE JOURNAL*, May 5, 1934, and Sept. 28, 1935) but it still retains many of the deficiencies pointed out in previous reviews. Some of the discussions, such as those on the estrogens and androgens, have been considerably expanded with the inclusion of much useful material.

A Manual of Operating Room Procedures. By Almira W. Hoppe, Science Instructor, Jewish Hospital of St. Louis, and Lucille M. Halverson, Supervisor of Operating Rooms, University of Minnesota Hospitals. Assisted by the Operating Room Nursing Staff of the University of Minnesota Hospitals. Boards. Price \$2. Pp. 239. Minneapolis: University of Minnesota Press, London: Oxford University Press, 1937.

The purpose of this small volume can be commended, and the tabulation of the necessary equipment for the routine surgical procedures shows evidence of thorough familiarity with such necessities and of excellent judgment in the avoiding of too detailed a discussion on the purposes of operations and the details of technique. It should not be assumed by those who use this book that on these two subjects the information is complete. For example, the statement that the "purpose of radium insertion in the vagina or uterus is to treat cancer" disregards the many cases in which radium is used for nonmalignant conditions. The possible difficulties arising from such incomplete information could easily be removed by a more inclusive statement as to the pathologic conditions for which the operation may be done.

The authors and the University of Minnesota Press have obviously had in mind the constant modification of old methods and the introduction of new ones, and the loose leaf binding will add materially to the usefulness of the manual in making it possible for one to keep pace with the advances in operating room procedures.

Synopsis of Ano Rectal Diseases. By Louis J. Hirschman, M.D., F.A.C.S., Professor of Proctology, Wayne University, Detroit. Cloth. Price \$3.50. Pp. 288 with 189 illustrations. St. Louis: C. V. Mosby Company, 1937.

Anything that comes from the pen of this author merits attention. In this little volume he has presented the common problems of proctology in a most interesting, concise and practical form. There are numerous illustrations, some of which are in color, which aid materially in clarifying the accompanying descriptions. The book was prepared by one whose unusual experience particularly fitted him for the task, and in his own words it is a synopsis of anorectal diseases.

Hemophilia Clinical and Genetic Aspects By Carroll LaFleur Btrch M.D. Assistant Professor of Medicine University of Illinois Bulletin Volume XXXI No 55 Illinois Medical and Dental Monographs Volume I No 4 Paper Price \$2 Pp 151 with illustrations Urbana University of Illinois 1937

This book is based on data from ninety-eight patients with hemophilia, studied from the point of view of the clinical manifestations, blood picture, diagnosis, course of the disease, transmission and genealogy. The family history and background of ninety-four of the patients are given in seventy-five charts and are summarized in tabular form. The photographs are unusually clear and graphic. Treatment is not considered separately, the discussion is limited to the clinical and genetic aspects. It is a valuable source book for physicians, research workers and geneticists interested in hemophilia. The monograph is useful as a supplement to the classics on this disease.

Menstruationsstörungen hormonalen Ursprungs Eine klinische Untersuchung Von P. N. Damm Paper Price 12 Danish kroner 10 marks Pp 285 with 21 illustrations Copenhagen Levin & Munksgaard Leipzig Johann Ambrosius Barth 1936

This small, well printed book contains a review of the literature on sex-endocrine factors in the human female with presentation of the author's own data. The subjects covered include cyclic changes in ovary and uterus, assay of estrogen in blood, urine and feces and determination of gonadotropic substance in blood and urine in the normal menstrual cycle in amenorrhea and hypomenorrhea and in menorrhagia and metrorrhagia, the effects of endocrine therapy are also discussed. Investigations of this type are highly important to an understanding of the physiologic basis of the menstrual cycle and to development of rational therapy of its disturbances. Physiologists and clinicians alike will find this a useful work.

Materia Medica Toxicology and Pharmacognosy By William Mansfield A.M. Ph.D. Dean and Professor of Materia Medica and Toxicology Union University Albany College of Pharmacy Albany N.Y. Cloth Price \$6.75 Pp 707 with 202 illustrations St. Louis C.V. Mosby Company 1937

Through excellent photographs that face the description of almost every individual drug discussed, this book should bring to the student's mind vivid pictures of the specimens seen in the laboratory and thus help him in his study and review. The section on toxicology aims to classify the poisons in such a way as to make it easier for the student to remember the symptoms of poisoning and treatment but the tests for the detection of poisons are not given. Unfortunately, the book seems deficient in that it makes no attempt whatever toward acquainting the student with the histologic appearance of the drug in its powder form, which is something most schools of pharmacy attempt to give their students, nor is there any attempt made at teaching the detection of adulterants.

Klinische Elektrokardiographie mit einem Grundriss der Arrhythmien Von Dr. Wilhelm Dressler Mit einem Geleitwort von Prof. Dr. C. J. Rothberger Fourth edition Paper Price 10.50 marks Pp 180 with 151 illustrations Berlin & Vienna Urban & Schwarzenberg 1937

In this edition the author has completely revised the text and replaced many of the illustrations in an attempt to keep the subject matter down to date. He has introduced the important subject of lead 4 and expanded the section on myocardial disease at the expense of the section on arrhythmias. He has continued the excellent plan of placing in italics the sections in each chapter dealing with clinical aspects. The advances made in electrocardiography are incorporated in simple language; the author shows his acquaintance with foreign as well as with German literature. The subject of arrhythmias so beautifully developed by the Viennese school is presented in clear and direct fashion. This book deserves its popularity.

L'année thérapeutique Médications et procédés nouveaux Par A. Ravina Onzième année 1936 Paper Price 20 francs Pp 175 Paris Masson & Cie 1937

In this volume, appearing annually, the author compiled reports of recent developments and progress in the field of therapeutics for the year 1936 most especially from French literature. Browsing among the numerous items abstracted, one notes the treatment of alcoholism by provoking intolerance by the smuggling of ipecac into the daily dose of liquor. Hot

baths are recommended as efficient in the treatment of urticaria and vitamin B in the neuritis of pregnancy. When local anesthesia relieves lightning pains of tabes but temporarily, alcoholization of the sensory nerve may produce a prolonged relief. In gastric crises, intravenous injections of 10 per cent saline solution antagonizes hypochloridemia. These few examples suffice to give an indication of the range of practical subjects covered.

Dr. F. G. Gades pathologisk anatomiske laboratorium i Bergen 1912-1937 [Dr. F. G. Gades Pathologic Anatomie Laboratory in Bergen 1912 to 1937] Paper Pp 107 with illustrations Bergen J. W. Eides Boktrykkeri A. S. 1937

In 1912 Dr. Gade who died in 1933 founded a laboratory in close affiliation with the city hospital of Bergen. This report covers the first twenty-five years of the activities of this laboratory. In addition to the statistical material—226 necropsies were made in 1936—there are interesting accounts of its history and organization and of special phases of its activities, notably on cancer, medicolegal examinations and extensive investigations of typhoid diseases in the western parts of Norway. The body of the report, as well as the list of publications at the end shows that the laboratory has been an active center of excellent practical and scientific importance from its beginning.

An Introduction to Medical Science By William Boyd M.D. M.R.C.P. F.R.C.P. Professor of Pathology in the University of Manitoba Cloth Price \$3.50 Pp 307 with 108 illustrations Philadelphia Lea & Febiger 1937

One is impressed by the very simplicity of presentation of this introduction to medical science. It "gives an airplane view of disease." There are three sections: the first deals with general principles of disease, the second with diseased organs and the final section with some practical considerations. Great care is exercised by the author to show the relationship between the lesions present and the symptoms produced. The book should prove of value to nurses, premedical students, hospital technicians and the general reader interested in matters of health and disease. There are numerous well chosen illustrations and a good index.

Entstehung und biologische Bekämpfung typischer Infektionskrankheiten Vorlesungen auf Grund der Ergebnisse experimenteller Untersuchungen Von Dr. med. Richard Bieling a. o. Professor für Hygiene und Immunitätswissenschaften an der Johann Wolfgang Goethe Universität Frankfurt a. M. Erste Folge Boards Price 6.60 marks Pp 119 with 7 illustrations Leipzig Johann Ambrosius Barth 1937

The author's plan is to present typical examples of different groups of infectious diseases by way of illustrating the nature and mode of origin as well as biologic principles of treatment and prevention. Two more booklets similar to this are to appear in the course of the next two years. The diseases so far discussed are diphtheria as the example of a strictly toxic infection, pneumonia as an example of the bacteremic infections, and epidemic poliomyelitis as an example of infections caused by filtrable viruses. Symptoms and diagnosis are not included in the discussion, which deals with the fundamental pathogenic nature, the immune reactions and the biologic treatment of the three diseases. No original points of view are presented.

Prostitution An Investigation of Its Causes Especially with Regard to Hereditary Factors By Tage Kemp Paper Price 10 kroner Pp 233 with 12 illustrations Copenhagen Levin & Munksgaard London William Heinemann Ltd 1936

This volume is based on investigations made in Copenhagen between 1931 and 1935. It concerns the records of 530 prostitutes, fifty of the case records being reported in full. This investigation seems to indicate that eugenic sterilization could have been of little value in preventing these cases of prostitution that childhood and youthful environment were in general bad and that there are many widely different factors which may be the immediate or the contributing causes of prostitution. The majority of prostitutes seem to be mentally a little abnormal. It is felt that well organized mental hygiene might be useful in controlling some of these cases and that there should be better coordination between the work of the police and of public welfare agencies in handling this problem.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Accident Insurance Lumbo-sacral or Sacro-Iliac Strain in Relation to Anomalies of Spine—The defendant insurance company, under a policy of accident insurance, promised to pay certain benefits to the physician-plaintiff if he was prevented from performing any and every kind of duty pertaining to his occupation as the result of an accident, independently and exclusively of all other causes. Dec. 25, 1932, in the course of answering a professional call, the physician slipped on an icy surface and, although he did not fall, wrenched his back. After the accident, he was wholly incapacitated and unable to attend to his usual professional duties. The insurance company refused to pay benefits for total disability and the physician brought suit against it. From a judgment in favor of the physician, the company appealed to the Supreme Court of Wisconsin.

The insurance company contended that the evidence showed that the physician's total disability was not due exclusively to accidental causes but was partly, if not wholly, due to conditions of health, and especially to an arthritic condition existing in the lower part of his back at the time of the accident. The company further contended that if the physician had sustained a sacro-iliac strain or sprain as a result of the accident, as he claimed, it should have been completely cured in from two weeks to three months in the absence of contributing causes. The defendant's contentions, however, did not meet with the Supreme Court's approval. In *Heithel v. Time Ins. Co.* 265 N. W. 575, it was held that, if a disease or bodily condition exists and an accident occurs, in order to constitute the accidental means the sole cause of an injury within the meaning of policies of accident insurance it is not necessary to show that the injury or the result thereof would have been as severe in the absence of the preexisting disease or bodily condition. It is sufficient if the accidental means would have solely caused some considerable injury had the disease or bodily condition not existed. The testimony of the physician's medical experts, said the court, entitled the jury to conclude that, while there were certain abnormalities of growth in the physician's spine, these were the result of advancing years or congenital anomalies and were not produced by or evidence of an active disease which contributed to his incapacity in cooperation with the accident. The physician's experts further testified that the injury resulted in lumbo-sacral or sacro-iliac strain and that his present symptoms and disability were solely referable to the strain. The court concluded that this testimony must be taken to mean that the accident "would have solely caused some considerable injury" had the physician's spine been in a normal condition.

Accordingly, the Supreme Court of Wisconsin affirmed the judgment in favor of the physician—*Egan v. Preferred Acc. Ins. Co. of New York (Ins.)* 269 N. W. 667.

Workmen's Compensation Acts Chronic Bronchitis Resulting from Escape of Chlorine an Accidental Injury—Not an Occupational Disease—Curley, an electrician, worked for about two months installing equipment to be used by the defendant corporation in manufacturing beryllium chloride. Some difficulty seems to have been experienced in adjusting the process of manufacture to local conditions and chlorine gas escaped at intervals into the room in which Curley was working until the process of manufacture was perfected. The plaintiff coughed frequently and became short of breath. Finally he had to quit work and seek medical attention. His attending physician diagnosed the condition as chronic bronchitis resulting from exposure to chlorine gas. Curley filed a claim under the Michigan workmen's compensation act but the department of labor and industry denied him relief on the ground that his disability was not the result of an accidental injury and hence was not compensable under the workmen's

compensation act. Without appealing to the courts from the department's determination, Curley instituted a common law action against his employer, attributing his disability to negligence on the part of his employer in failing (1) to provide him with a safe place in which to work, (2) to warn him of the danger of chlorine gas, and (3) to furnish him with protecting safety appliances. The trial court directed a verdict for the employer and Curley appealed to the Supreme Court of Michigan.

The Supreme Court of Michigan affirmed the judgment of the trial court. It pointed out that the enactment of the Michigan workmen's compensation act conferred exclusive jurisdiction on the department of labor and industry in the first instance with respect to accidental injuries arising out of and in the course of employment, that Curley's disability was the result of an accident—the escape of chlorine gas—and not to an occupational disease, that Curley's sole remedy was under the workmen's compensation act, and that he should have appealed from the determination of the department of labor and industry to the courts—*Curley v. Beryllium Corporation (Mich.)*, 270 N. W. 202.

Evidence Admissibility of Complaints Made to Physician Examining to Qualify as Witness—The declarations of a person as to his symptoms, made to a physician not for the purpose of treatment but to aid the physician to form an opinion for the purpose of testifying as a witness for the declarant in a suit brought for personal injuries, said the Court of Errors and Appeals of New Jersey, are not admissible in evidence at the instance of the declarant. An expert witness for the defendant, however, in an action for damages for personal injuries may not only properly testify as to the conduct and result of his examination of the plaintiff but may also testify to any relevant statements made to him by the plaintiff with regard to the accident which caused such personal injuries—*Sandford v. Chanaz Co. (N. J.)*, 189 A. 670.

Practice of Embalming by Cooperative Association Illegal—The state of Iowa sought to enjoin the Fremont Co-operative Burial Association, a corporation which supplied embalming and funeral services and burial supplies to its members when deaths occurred in their families, from engaging in the practice of embalming. From a decree of the trial court granting the injunction, the defendant association appealed to the Supreme Court of Iowa.

The defendant admitted that a corporation cannot lawfully practice a profession and that, as a corporation, it could not engage in embalming without violating the law. It contended, however, that the practice of a profession by a corporation was not involved in this case and that the real question presented was whether the employment of a licensed embalmer by an incorporated nonprofit cooperative association to render professional services as an embalmer to its members only constituted the practice of the profession of embalming by the corporation. Apparently, the defendant admitted that if the employment of the licensed embalmer by it, and the furnishing of his services to the public generally, were a part of the business conducted by it, there would be a violation of the law. But it contended that the services of its licensed embalmer were furnished only to the members of the cooperative association and that therefore there was no selling by it of professional services to the general public, and hence no violation of the law.

That a corporation, said the Supreme Court of Iowa, cannot legally furnish professional services to the public generally through or by means of employing licensed members of a profession, for whose services it makes charges that go into the funds of the corporation, seems to be definitely settled in Iowa. The effect of the articles of incorporation of the defendant corporation and its by-laws, in the opinion of the court, was that any person residing within 35 miles of the town in which the corporation operated might avail himself of its services whether or not he was a member of the association at the time the services were required. If, for instance, a death occurred in the family of a nonmember, the head of the family or any person on whom would devolve the duty and liability of providing a burial for the deceased, even though he or

had never heard of the corporation and had no thought or intention of belonging to it prior to that time, would only have to go to the place of business maintained by the corporation, or to some one authorized to accept membership therein, and pay the membership fee. On such payment the family in which the death had occurred would immediately be entitled to the benefits of the association, including the services of the licensed embalmer. A person applying for membership under such circumstances would have to pay a membership fee of \$15 instead of a fee of \$10 ordinarily charged members, but the court did not think that this increased fee could be used as a standard or criterion by which to determine bona fide membership in a cooperative association. The benefits of such an association, depending on the death of a person should not be extended to cases in which neither the person claiming the benefits nor the deceased person was a member of the association at the time the death occurred. To permit the business of the corporation to be thus conducted, the court said, and the benefits of membership in it to be thus extended to the public generally, regardless of membership in the association at the time the death occurred would be to approve of a scheme and a subterfuge that would permit the corporation to evade the purpose and provisions of the law.

The court did not determine whether an incorporated association, such as the one here involved, could legally furnish the services of a licensed embalmer to its members, if membership in the association was restricted by reasonable and legitimate requirements. Under the record in the case, the court concluded that the requirements as to membership were not such as to confine the benefits of the corporation to a bona fide body of members but extended the benefits to the public generally within a distance of 35 miles from the place of business of the corporation.

The decree of the lower court enjoining the corporation from practicing embalming was therefore affirmed.—*State v Fremont Co-operative Burial Ass'n (Iowa)*, 270 N W 320

Privileged Communications When Privilege Attaches to Examination of Patient—In the trial of the present case for compensation under the Michigan workmen's compensation act it became material to determine whether or not a child was an offspring of the marriage of the deceased workman and his first wife. His second wife, the appellant herein, offered to prove that the first wife and the workman both went to certain physicians to determine why their marriage had been without issue, that the examinations indicated that the workman was incapable of reproduction because of a prior gonorrhea and double epididymitis, that subsequently the first wife gave birth to the child in question, and that later a second examination of the workman by the same physicians failed to change their original conclusions. The trial court refused to allow the physicians to testify, holding that their testimony was privileged under 3 Compiled Laws of Michigan, 1929, section 14216, reading in part as follows:

No person duly authorized to practice medicine or surgery shall be allowed to disclose any information which he may have acquired in attending any patient in his professional character and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon.

From that ruling of the trial court, the second wife appealed to the Supreme Court of Michigan.

The appellant contended first that the privilege, if any, was waived because of the presence of the first wife at the examination of the workman. But, said the Supreme Court, the presence of an intimate family relation at the time of consultation should not and does not waive the privilege. The appellant next contended that the information obtained by the physicians was not privileged because the workman and his first wife had gone to the physicians for examination only and not for treatment, citing *In re Bruendl's Will* 102 Wis 45, 78 N W 169. In the Bruendl case, said the Supreme Court, the matter or treatment by the physician was wholly foreign to the purpose of the visit. No treatment was contemplated. Instead the woman examined in that case sought to establish that her sterility was such that a guardianship over her should be removed. In the present case the workman and his wife went

to the physicians for the purpose of ascertaining why a child or children were not born of their union. Confidential communications followed, as well as several examinations and tests from which it was ascertained that the workman was incurably impotent. The workman and his wife were desirous of having offspring and the inference necessarily arises that, if curative or remedial measures were available, such were contemplated. The privilege arises between a physician and his patient notwithstanding the patient's condition as disclosed is not subject to treatment. *Grattan v Metropolitan Life Ins Co* 24 Hun (N Y) 43. In the present case the workman examined subsequently died. After the death of the patient, the privileged matter is all the more sacred and the protection of the patient continues unless waived by some one authorized to do so. The court was of the opinion that the second wife was not authorized to waive the privilege.

The Supreme Court held, therefore, that the trial court properly refused to admit in evidence the proffered testimony.—*Bassil v Ford Motor Co (Mich)* 270 N W 258

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Impending Coronary Artery Occlusion—In contrast to the occurrence of progressive angina pectoris, it has been apparent to Sampson and Elaser, on observation of twenty-nine cases extending over two and one-half years, that a single spontaneous attack of prolonged anginal pain strongly suggests the approach of a typical coronary thrombosis. Certain characteristics of these attacks of pain seemed to be so well defined that several patients were put to bed either at home or in a hospital from one to fourteen days prior to the development of the typical symptoms and signs of the arterial block. An interesting clinical comparison may be drawn between the diagnosis of impending coronary artery occlusion and impending occlusion of an intestinal artery. Dunphy defined the typical features of the latter condition and quoted a case history of premonitory pain occurring two months prior to death from the acute block of gradually thrombosing celiac axis and inferior mesenteric arteries. With a rich collateral blood supply, acute symptoms and signs of the blockage may never develop. This may account for the rare "silent coronary occlusion" seen at necropsy. The duration of the warning attack varied from two minutes to two hours, averaging sixty-three minutes in individuals without a history of angina pectoris and from fifteen minutes to fourteen hours, averaging two hours and forty minutes in patients with that history. There were only seven patients who had pain of less than twenty minutes' duration. No premonitory attacks occurred during sleep, and strenuous exertion occasionally preceded the pain. The interval between the premonitory attacks and the major attacks of the entire series varied between one and twenty-one days. The electrocardiograms taken were chiefly notable in that they offered no demonstrable assistance in making a diagnosis of impending thrombosis. Electrocardiograms taken after their occlusive attacks showed characteristic pathologic changes. There was a fatality of 34.5 per cent in the patients with the premonitory syndrome in the twenty-nine cases. The diagnosis of the premonitory syndrome is made

difficult because certain patients seem to present some of the characteristics mentioned previously but fail to develop the typical signs of a coronary artery occlusion within a period of weeks afterward.

Cancer of Mamma—Cramer believes that the experimental production of cancer of the mamma by estrogen has enlarged the outlook on the etiology of cancer by demonstrating the existence of a carcinogenic environment which is entirely internal. In that respect there is an essential difference from the experimental carcinogenesis of the skin when the decisive factor is a carcinogenic agent acting from without and when the carcinogenic environment is partly external and partly internal. The existence of a carcinogenic environment which is entirely internal enables one to understand why a malignant condition can develop in organs not exposed to influences coming from without why it is possible to obtain by inbreeding pure strains of mice with a high incidence of spontaneous cancer in one organ—the mamma—but not in another—the skin, and why such pure strains show considerable differences from one another and from mixed strains in the response of the mamma to the carcinogenic action of estrogen, while in the same strains no such differences are found in the response of the skin to the chemical substances carcinogenic for the skin. In man the familial incidence of cancer shows corresponding differences between the mamma, when the familial incidence is high, and the lip, when it is low. The inference is that cancer of the breast in women—at least in those with a family history of cancer of the breast—is the result of an internal carcinogenic environment. Since in mice this internal carcinogenic environment is associated with abnormalities in the endocrine system a search for such abnormalities in women with cancer of the breast and a family history of cancer of the breast is indicated.

Tuberculosis in Young Children—From a study of 349 infants infected with tuberculosis during the first five years of life and observed for from one to nine years, Rosenberg and Kereszturi found that the rate of deaths from tuberculosis

was 91 per cent. Of the patients for whom roentgenograms of the chest were taken, 289 per cent presented parenchymal lesions of the lungs. The rate of mortality from tuberculosis among the Negro children was about twice that among the white ones. The incidence of parenchymal lesions of the lungs also was higher in the Negro group. The rate of deaths from tuberculosis among 175 children infected with the disease during the first year of life was 14.8 per cent; the fifty-nine who were infected during the first half of the second year showed a rate of 10.2 per cent. The highest rate, 43.7 per cent, occurred in the children infected during the first three months of life. No deaths from tuberculosis occurred in the group of 114 children infected after reaching 18 months of age. All the deaths from tuberculosis occurred in children less than 3 years of age. The rate of deaths from tuberculosis was more than five times as high in the children with parenchymal lesions as in those with enlarged tracheobronchial glands, and about eight times as high as in those who gave no roentgenographic evidence of having tuberculosis.

Blood Transfusions in Primary Pneumonia—According to Arena, during the last three years, efforts were made at the Duke Hospital to give one or more blood transfusions to all infants and children who had severe primary pneumonia, whether or not they had anemia. However, because of the difficulty in obtaining suitable donors, thirty-five patients did not receive blood and consequently served as controls. The other twenty-four had one or more transfusions of citrated blood by the gravity method (maximal amount, 20 cc per kilogram of body weight). The clinical symptoms, hemoglobin content and red and white blood cell count for the two groups were almost identical. The only difference which could be noted was that in the group who received transfusions there were probably more ill patients and more infants. Prompt and marked symptomatic improvement usually followed the transfusion, and the patient appeared more comfortable. The temperature fell by crisis within twenty-four hours of the transfusion in fifteen cases and within forty-eight hours in the other nine. The average interval between the onset and the crisis or lysis for this group was seven and nine-tenths days. Four of these children had the complication of suppurative otitis media, and one died. For the thirty-five patients who did not receive transfusions, the average interval between the onset and the crisis or lysis was nine and nine-tenths days. Three of these children had the complication of empyema, and nine had otitis media. Five died. The severe dyspnea and cyanosis which many of these children had were improved instead of made worse by the transfusions. Possibly, transfusions stimulate an increase in segmented polymorphonuclear leukocytes. The hemogram studies which have been made for several patients with primary pneumonia indicate that improvement or a crisis is attempted by an increase in the segmented polymorphonuclear leukocytes with a decrease in the percentage of nonsegmented forms. The ratio of segmented to nonsegmented forms appears to be a good indication of the severity of the infection and the ultimate outcome. Perhaps transfusions are a form of serotherapy, introducing neutralizing antibodies or causing non-specific protein shock. Another factor may be the supplying of cells to carry needed oxygen to the tissues, the replacing of those withdrawn from the circulation by the pathologic process.

Nutrition and Basal Metabolism of Children—Maroney and Johnston measured the dietary intake of thirteen girls, aged from 5 to 12 years, and fourteen boys aged from 4 to 14 years, over periods averaging nine and four-tenths months; their nitrogen balances were noted for an average of 111 days for each child, and periodic observations on their basal metabolism were made. Caloric and protein requirements per unit of height and weight were recorded for each child. Gain in weight and height was obtained with caloric intakes representing increments over the basal calories averaging 67 per cent for the girls and 74 per cent for the boys. With calories adequate for growth, intakes of protein representing 15 per cent of the total calories seemed optimal. Amounts greater than 20 per cent were usually productive of pallor, loss of appetite, abdominal discomfort and sometimes vomiting. With amounts less than 15 per cent a

negative nitrogen balance or depression of the basal metabolism was frequently observed. The so called sparing effect of fat and carbohydrate on protein was reexamined and confirmed, thus constituting an argument for recording the protein requirement in terms of the percentage of calories rather than of grams per unit of weight.

Chronic Myelogenous Leukemia—Stephens presents detailed observations of the peripheral blood, bone marrow, nitrogen balance and oxygen consumption in two patients with typical chronic myelogenous leukemia before and during satisfactory remissions induced by solution of potassium arsenite and by roentgen therapy. In each instance treatment was followed by clinical improvement, reduction of the total leukocyte count to a normal level, marked decrease in immature cells, reticulocytosis, improvement in the anemia, return of the oxygen consumption to a normal level and striking changes in the bone marrow. In each instance the gray, hyperplastic, cellular leukemic bone marrow was replaced (presumably temporarily) by a relatively hypocellular, fibrotic marrow and the markedly increased myeloid erythroid ratio was decreased to an approximately normal level. Roentgen therapy was followed by a marked increase in the nitrogen excretion. The administration of solution of potassium arsenite was followed by no significant change in the nitrogen balance.

Febrile Albuminuria—Welty studied the relation of fever to albumin in the urine in forty patients receiving fever therapy. The patients treated were suffering from dementia paralytica, atrophic arthritis, gonorrheal arthritis and chorea. All had a blood urea nitrogen within normal limits, a normal Mosenthal concentration test and several negative examinations of the urine for albumin. Fever was induced by means of the Kettering hypertherm and an average temperature from 105 to 106 F was maintained for from four to six hours. A specimen of urine was obtained before the febrile period; a second specimen was collected after the fever had reached its height and had been maintained for several hours; the third specimen was the first urine voided after the temperature had fallen to normal. These urines were then examined as to specific gravity, reaction to litmus paper and for gross albumin by the sulfosalicylic acid reagent. The exact amount of urinary albumin was determined by the quantitative sedimentation method of Skevly and Stafford. In 95 per cent of the subjects the prefever urine albumin was below 0.03 per cent and 80 per cent presented a figure below 0.02 per cent. The urine albumin exceeded 0.04 per

cent in only one case. These are normal values and offer better proof of absence of renal disease in the group than the blood urea nitrogen and the Mosenthal test. During the febrile period 22.5 per cent of cases showed a decrease in albumin with fever, while 77.5 per cent had an increase in the level of urine albumin. This increase was very definite, being more than 100 per cent in twenty of the subjects and more than 200 per cent in sixteen cases. On four occasions the albumin level increased 500 per cent. In spite of the rather large percentage rise, the actual albuminuria is not likely to be massive. During fever only nine of the forty cases showed albumin in the urine as determined by the sulfosalicylic acid method. The patients had a temperature elevation for only a few hours, but had this been maintained for days, as is the rule in infectious fevers, it is probable that larger amounts would have appeared. Comparison of the prefever and postfever urine albumin levels indicated that 70 per cent of the subjects continued to show an increase in albumin in the specimens voided after return of the temperature to normal. This suggests that the increased output is carried over into the postfever stage, the possible delay in voiding, however, must be considered in evaluating these results.

Visceral Pathology in Measles—Degen made a study of the pathologic changes found throughout the body in 100 deaths from measles. In analyzing the pathologic observations in these cases, he found the most striking observation to be the absence of any specific gross or microscopic pathologic lesion which, in the absence of additional clinical data, could lead to a diagnosis of measles. The most constant pathologic change appears to be pneumonia and inflammation of the upper part of the respiratory tract, but even the pneumonia is not of a single type. Elsewhere the gross picture is one of secondary infection and concomitant toxic changes, the infection being most often apparently of a streptococcal nature. Microscopic examination also shows evidence chiefly of a severe and widespread toxic and infectious process. Among these changes, the frequent presence of an interstitial, mononuclear cell infiltration is of especial interest. A purely interstitial mononuclear infiltration was observed in the measles series in practically all of the twenty-two sections of the trachea, in twenty of the eighty-nine liver sections, and in from one to six cases each in the heart, kidney, adrenal and pancreas. The eleven skin sections examined all showed slight mononuclear cell infiltration of the corium. Slight endothelial cell changes were observed in four of these, but in none were there the marked changes and proliferation of these cells described in measles rashes by Ewing, Mallory and Medlar, and Denton. Bacteriologic studies at necropsy showed the hemolytic streptococcus, either alone or in combination with other bacteria, to be overwhelmingly the chief organism present. No lesion definitely pathognomonic of measles was found.

Relapsing Alternating Peripheral Facial Paralysis—His observations in two cases lead Viole to agree with Tumarkin that the presence of pain at the onset of a facial palsy and the disturbance of taste are of great prognostic significance. In the first instance the patient did not complain of either of these symptoms and recovery apparently is complete. These two symptoms were definitely present in the second case reported, and there is still noticeable residual involvement. The phenomenon of synkinesis, as described by Tumarkin, plainly exists in the second patient. Disturbance of the facial nerve also undoubtedly influences the act of deglutition, as is demonstrated in the latter case. The premonition of onset experienced by the first patient, the author believes, is of interest and probably has existed in other instances. These two cases of relapsing alternating peripheral facial paralysis are presented mainly because similar cases must be of more frequent occurrence than is evident by the scarcity of reported instances in the literature.

Cause of Dizziness in Head Injuries—Glaser analyzed sixty-six cases of dizziness from a series of 325 cases of head injury in order to determine the cause of dizziness in head injuries and the value of vestibular tests as a diagnostic adjunct, as well as the ability of the patients to prognosticate the duration of dizziness. The vestibular tests are of no value in determining either the type of dizziness or the presence or absence of dizziness encountered in these patients, nor by them can the duration of dizziness be prognosticated. They do, however, in certain cases, reveal the presence of pathologic change within the brain and thus corroborate, to a degree, the truth of the patient's story with regard to a head injury. In this manner they are indirectly of value in eliminating the malingerer. It is quite evident that the common types of dizziness associated with head injuries are not dependent on definite vestibular lesions, instead, it is likely that they are due to an entirely different mechanism possibly transient cerebral vasomotor disturbances. Encephalograms and vestibular tests, performed on four patients, both demonstrated pathologic changes in the central part of the brain. In two of these patients dizziness was entirely absent. Vestibular tests performed in

sixty-six cases revealed subjective symptoms in 80 per cent, objective neurologic signs in 21 per cent and vestibular abnormalities in 76 per cent. Objective signs were thus demonstrated more frequently by vestibular examination than by clinical neurology. Though no distinct vestibular complex was associated with head injuries, there were certain predominant observations. Normal vestibular responses may indicate either an undamaged brain or a brain evidencing pathologic change which has not involved the vestibular pathways. Lesions of the end organ signify peripheral involvement of the vestibular fibers, while central lesions indicate pathologic changes either directly present or adjacent to the central vestibular pathways.

Cause of Death in Tularemia—Foshay's experience and a study of case records indicate that the chief cause of death attributable to tularemia alone is septicemia due to *Bacterium tularensis*. Pneumonia that originates from the primary bacteremia does not become associated with fatalities unless septicemia supervenes. At least 70 per cent of the cases of tularemic pneumonia do not result in death. In a small number of cases, probably much smaller than the proportion in this series indicates, the primary bacteremia is septicemia from the onset and causes a rapidly fatal termination in from four to ten days. These unfortunate persons have apparently no natural resistance to the infection. The septicemia that causes most fatalities originates from a second invasion of the blood stream. Tularemia is especially dangerous to persons with preexisting coronary heart disease. Death may occur in such cases from coronary occlusion or acute myocardial failure during the initial acute phase or during convalescence. The surviving patient may suffer attacks of angina pectoris, coronary occlusion and heart block for years after recovery from tularemia. The third week of infection is the most dangerous period and most deaths occur on the sixteenth day of illness. It is estimated that four of every five deaths from tularemia could have been prevented by the early administration of serum therapy.

Monocytic Leukemia—Montgomery and Watkins make a distinction between monocytic leukemia of the Naegeli and that of the Schilling type on the basis of the hemocytologic pictures. Either type may be of primary autochthonous cutaneous origin. The type of cutaneous manifestations of either condition may be specific or nonspecific and may vary from discrete necrotic nodules or purpuric lesions to generalized exfoliative dermatitis. A distinctive histopathologic picture of monocytic leukemia of the Schilling type may be observed on examination of the skin, corresponding to the hemocytologic picture. Occasionally, myelogenous leukemia may terminate as monocytic leukemia of the Naegeli type or lymphatic leukemia may result in monocytic leukemia (Schilling) and still later again present the blood pictures of both conditions. Monocytic

leukemia of the Schilling type (leukemic reticulo-endotheliosis) may assume an acute or chronic form, and even aleukemic reticulosis may be encountered. The cutaneous as well as the general clinical, pathologic and hemocytologic observations should be correlated in a given case in order to arrive at a correct diagnosis. A prolonged period of observation may be necessary before it is possible to ascertain the type of lymphoblastoma that will eventuate.

Drug Therapy in Angina Pectoris—Riseman and Brown investigated the use of fifteen different drugs in the treatment of twenty-six patients with angina pectoris. Each drug was given several times a day for at least a week before its effect was evaluated. The patient's estimation of therapeutic benefit indicated that all the drugs were approximately equal in value. Placebos were just as often beneficial as other medicaments. The exercise tolerance test revealed that patients whose treatment consisted of lactose, sodium bicarbonate, potassium iodide or tissue extract were unable to perform any more work than was possible without medication. Glyceryl trinitrate given before work was undertaken prevented attacks and enabled many patients to do considerably more work. Thus prophylactic effect was often of relatively short duration, but attacks were prevented for as long as an hour in many cases. Such patients could be rendered completely free from attacks in daily life by taking glyceryl trinitrate at hourly intervals. For all practical purposes small doses ($\frac{1}{1000}$ grain or 0.1 mg) were as valuable as larger doses and were attended by little discomfort. One half of the patients were benefited by either aminophylline or quinine sulfate. Theophylline calcium salicylate, erythrol tetranitrate and atropine sulfate were often of value occasionally they benefited patients not helped by either aminophylline or quinine sulfate. Codeine sulfate and phenobarbital rarely enabled the patient to do more work before pain developed, but these sedatives appeared to be of aid as an adjunct in the treatment of the patient. Digitalis was rarely of value and frequently caused a striking increase in anginal attacks.

Boeck's Sarcoid—Nickerson believes that in his six cases, in which necropsies were made the lesions were found for the first time in the myocardium, endocardium, pancreas, testis and vertebral and femoral marrow. Lesions were found in the spleen in five cases, with definite splenomegaly in four, and in the lungs in four cases. In differentiating sarcoid from tuberculosis, especially the miliary form the following points are of assistance: 1 Caseation should never be present. In none of the lesions of sarcoid are any neutrophilic polymorphonuclear leukocytes seen, an observation one would expect in an early caseating tubercle. 2 The giant cells are different from those seen in tuberculosis. They show moderate variation in size, are usually much larger and contain many more nuclei which are evenly distributed throughout the cell and are seldom arranged in the elliptic manner typical of tuberculous giant cells. 3 Lesions in tissues other than the lungs do not contain carbon pigment. 4 In the liver the lesions are most numerous in the portal tracts with only a few in the midzones of the lobules. In miliary tuberculosis the reverse is true. 5 With silver impregnation, a delicate reticulum is always present in the lesion. In tuberculosis this is destroyed by the onset of caseation. 6 No evidence of tuberculosis is found anywhere in the body. Giant cells may occur in all stages of the disease. The amount of collagen present seems to be a more accurate index of the activity of the infection. In the only case in which a

minimal amount was present, death was apparently due to this disease, an occurrence suggesting that an increase indicates a healing reaction. The presence of increased amounts of collagen indicates a healing reaction. Sarcoid-like lesions are composed of small irregular foci of elliptic macrophages with occasional areas of fibrosis and rare giant cells or lymphocyte infiltration, differing from true sarcoid in that they lack the smooth outline and cellular infiltration of the latter. While they may thus be distinguished their significance and possible relationship are not yet entirely clear.

Talcum Powder Granuloma—Fienberg presents two cases of granuloma caused by anisotropic crystals shown to be talc (magnesium silicate). Three cases are described of similar lesions in which the crystals were morphologically similar to talc crystals. Lesions similar to those found in these cases were produced in mice by talc. An analysis of the cases revealed the diagnostic errors caused by talc crystal granuloma under varied circumstances. The value of examination of suggestive sections under crossed Nicol prisms is stressed. The indiscriminate use of talcum powder in the operating room may produce granulomatous lesions.

Fatty Acids in Relief of the Common Cold—Following a control period of seven weeks, beginning January 1, during which colds were recorded, Boyd and Connell gave 15 minims (1 cc) of purified linoleic and linolenic acids (vitamin F) daily to forty-one medical students for a further seven weeks, while sixty-five others served as controls. Vitamin F reduced the average incidence of colds by 64 per cent and the average duration by 78 per cent there being at the same time little appreciable difference in the incidence and duration of the untreated group. Of the treated group 71 per cent responded favorably and 29 per cent showed no relief. Unpleasant reactions occurred in one third of the treated cases, diarrhea, nausea and vomiting being the chief side effects, but most of these were temporary and disappeared when the substance was taken with, rather than between meals.

- *Obstetric Anesthesia and Analgesia Their Effect on Third Stage of Labor T L Montgomery Philadelphia—p 119

Procedure in Third Stage of Labor—Montgomery considers the following a conservative and safe procedure in the third stage of labor. 1 The fetus having been delivered for instance by low forceps and episiotomy, the anesthetic is at once stopped. 2 The uterus is palpated and then entrusted to

a nurse, and the episiotomy is inspected to see that there is no large vessel bleeding. 3 Mucus is removed from the fetal air passages and resuscitation attended to. 4 In the meantime a half ampule of solution of posterior pituitary is given to the patient and the nurse reports on the condition of the uterus. 5 The baby's eyes are treated, the cord is dressed and the child is taken to the nursery. 6 The uterus is palpated and, when the typical signs of placental separation occur, the placenta is expressed. An ampule of an active ergot product is given deeply by hypodermic. 7 The uterus is massaged and held until it is consistently hard and only then entrusted to the nurse again. If bleeding is excessive, it is packed at once. 8 The placenta is examined and its completeness ascertained. 9 Precise inquiry is made as to the pulse, rate and volume and the condition of the patient. If the report is favorable, immediate repair of the birth canal is decided on. If it is not completely favorable, the repair is postponed six or eight days or even two or three months. 10 If conditions permit of repair, anesthesia is reestablished, the parts are thoroughly reprepared, the operator's gloves (and gown too, if necessary) are changed, and the repair is performed in good light, with good exposure, and with the same care as a gynecologic perineorrhaphy. 11 The operation completed, the parts are dressed, the uterus is palpated, the pulse tested and the baby examined. 12 After dressing, the operator reexamines the mother and the baby and does not leave until an hour has passed. Such a routine ensures the recognition and prompt treatment of shock and the immediate arrest of hemorrhage. It has served the author well in many a difficult situation. The third stage of labor and the placental separation merit the most careful attention of the operator and are not to be complicated by continuing anesthesia and attempting to suture extensive episiotomies or lacerations while waiting for their completion. Labor should be completed, the patient made sure of and the damage repaired.

Source of Neutralizing Principle for Vaccinia—McMaster and Kidd aver that their data prove that the regional lymph nodes elaborate an antiviral principle when virus is brought to them by way of the lymphatics from the injected ear of the rabbit and that this is demonstrable within four days after the inoculation of virus. The experiments indicate that it could probably be demonstrated even after a shorter time, following an injection of virus in the ear were better testing methods utilized, as for example if protective substances and virus were separated by filtration or by electrophoresis. The antiviral principle was present in greater concentration in the extract of the lymph nodes of the virus injected side than in the undiluted blood serum procured at the same time, and in far greater concentration than in the serum diluted equally with the node extract. The possibility would seem to have been excluded that an antiviral principle developing in the injected ear or elsewhere in the body accumulated in the lymph nodes, thus accounting for the condition found. The control injections of typhoid vaccine inflamed both the injected ear and the nodes, draining it, but no antiviral principle was ever found in either until long after their appearance in the nodes of the virus injected side. The antiviral principle developed first in the nodes. The circumstances were much like those of natural infection and like those of artificial vaccination. The immune

following clinical vaccination may well be of lymph node origin in great part. The relative amounts of antiviral principle present in the various organs or body fluids change much with the lapsed time after virus infection. The results in any individual case may depend largely on the port of entry of the virus, on the quantity entering and on whether it spreads rapidly or is retained by one tissue or organ.

Tribrom-Ethanol as Relaxing Agent in Removal of Calculi—Jarman and Scott employed the following technic in twenty-seven patients. After admission to the hospital the patients are placed on sodium acid phosphate and methenamine even though infection is absent. Fluids are forced and medication given, if necessary, to relieve the pain. A number 5 F ureteral catheter, when possible, is passed by the obstruction to the kidney. This ensures good drainage and protects the kidney. After this bougies or catheters of such size and number as the obstructed ureter will permit are passed to the kidney. The patient is returned to the ward with instructions to drain the catheters in a sterile urinal for forty-eight hours. At the end of this time the patient is brought to the clinic for the tribrom-ethanol injection. This solution is prepared freshly and aseptically, by dissolving 1 Gm of tribrom-ethanol crystals in 50 cc of warm sterile, distilled water. This 2 per cent solution is then injected, while warm, directly through the indwelling catheter into the kidney pelvis, the amount injected being determined by the pain produced from moderate distention of the pelvis. The catheter is then plugged and the patient requested to sit upright in order to facilitate the passage of some of the solution down along the ureter. This is allowed to remain in contact with the pelvis and ureter approximately fifteen minutes. Then the instruments are withdrawn, at which time they are slowly twisted and more solution is injected directly into the lumen of the ureter. The patient is then instructed to void in the erect posture. In three instances the obstruction due to

stone was so marked that with the patients prepared for cystoscopy in the usual manner it was impossible to pass a catheter beyond the calculus. After the rectal administration of tribrom-ethanol as a basal anesthetic to each of these patients three instruments were easily passed beyond the calculus. With this method the calculus was recovered in twenty-five instances (92.5 per cent). In thirteen instances (48.1 per cent) the stone was recovered as soon as the patient voided.

Specialization in Medicine Subject for Undergraduate Planning II Cabot Rochester Minn—p 24

Endometriosis of Colon and Rectum—Among 104 patients with endometriosis who have been treated at the Lally Clinic, seventeen have had involvement of the sigmoid colon or rectum (16.3 per cent). Cattell divides these cases of endometriosis into three groups, which are based on the extent of the involvement of the intestine and the indications for treatment: (1) endometriosis of the rectovaginal septum, (2) endometriosis involving the serosal and muscular coat of the intestine owing to its juxtaposition to a generalized endometriosis in the ovaries tubes or uterus and (3) endometriosis involving the entire intestinal wall. All three groups may show obstructive symptoms, although in the third the obstruction is more marked and is more readily confused with carcinoma. In patients with rectovaginal involvement a biopsy to establish the diagnosis should precede the abdominal operation. If the rectovaginal involvement is extensive and is producing a severe obstruction a bilateral oophorectomy is indicated, with or without colostomy. Colostomy, if done, is temporary and can be closed after a few months. The treatment of the cases with involvement of the rectosigmoid and rectum due to extensive endometriosis in the pelvis is radical so far as the uterus, tubes

and ovaries are concerned. The author has felt it advisable to remove the endometrial cysts encroaching on the lumen of the intestine, as well as the ovaries, although the dissection of the cyst on the intestine is likely to be tedious and time consuming if one is to avoid injury to the intestine. No resection of the intestine was performed nor was a colostomy necessary in this group of eight patients. The treatment of discrete implants involving all layers of the sigmoid is a more difficult problem, owing to their infrequent occurrence and their similarity to carcinoma. All four patients in this group (3) were operated on because of intestinal obstruction. One patient was submitted to an abdominoperineal resection because of a diagnosis of carcinoma (the ovaries were not removed), two had a modified Mikulicz type of local resection since their condition was suspected of being endometriosis at the time of operation (the ovaries were removed in one) and the fourth patient had a bilateral oophorectomy without resection of the intestine. In a more recent case in which a solid tumor of the cecum was found, a frozen section diagnosis of endometriosis was of value. In this patient there was no obstruction, so bilateral oophorectomy was done and the cecal tumor was left in situ. In the presence of an intestinal obstruction that is not severe, it seems safe to remove the ovaries without resecting the intestine if the diagnosis of endometriosis is confirmed by frozen section. Resection should be carried out in patients in whom carcinoma cannot be excluded. If the diagnosis is not certain and resection is performed, and if examination of the resected specimen shows that the lesion is an endometrial implant, the ovaries should be removed. The results of the surgical treatment of endometriosis are and should be satisfactory. There has been no operative or subsequent mortality in the seventeen cases in which intestinal involvement was present. Of the five patients in the first group three have no remaining tumor, one has no symptoms although a small mass remains and the fifth patient was treated after biopsy by x-ray therapy and is unimproved. In group 2, five patients are free of symptoms, but, in spite of removal of both ovaries, barium sulfate enemas show narrowing and spasm of the intestine. All the patients in group 3 are well. Of the three patients who had a resection, one developed acute abdominal symptoms that suggested intestinal obstruction three months after operation. These subsided without operative intervention and the patient has subsequently remained well for more than two years.

Pyuria in the New-Born—Miller reviews forty-seven cases of pyuria of the new-born from the literature and from the files of the Infants Hospital in Boston. Urinary examination is urged as a procedure in the explanation of symptoms of infection in the new-born and as a routine procedure in the well baby care of the new-born. The incidence of pyuria seems to be about equally divided between the males and the females, in

contrast to the disease in older children, in which the females predominate. Symptoms are not always present and when present are those of any acute infection in this age group. All cases which came to necropsy showed inflammation in the kidney substance and none in the pelvic walls. In no case could congenital anomalies of the urter be said to play a major part in the original etiology, and even in the few cases which showed stenosis and megaloureter, every indication seemed to indicate that they were secondary to the infection or incidental. The pathologic observations on these patients seem to match observations made by Helmholtz on rabbits infected by the hematogenous route, that pyuria in the new-born is a so called descending infection, most probably hematogenous in the majority of cases. The most important consideration in treatment is to promote a diuresis, and the most effective method is to give fluid by mouth and dextrose solution intravenously in rather large quantities if there is vomiting, new-born babies seem to have little resistance to *Bacillus coli*, indicating transfusions. This should be given intravenously, since the best clinical results in infections of the new-born are obtained in this manner. If the patient survives the neonatal period and the pyuria persists, the same considerations hold for investigation and treatment as in any baby with pyuria of comparable age.

Low Temperature Ball Mill for Liberation of Labile Cellular Products S Mudd C H Shaw E J Czarnetsky and E W Flossdorf—p 887

Trichinosis and the Garbage-Fed Hog—Hall considers the role of the garbage-fed hog in the production of human trichinosis. The common occurrence of pork scraps, including those not adequately cooked or processed as to kill trichinae, in garbage and swill, and the eating of such scraps by large numbers of swine, are well established facts. There are, usually, approximately from thirty to forty million hogs slaughtered annually in the United States, and the scraps of pork from these millions of hogs are trimmed out in butcher shops, hotels, homes and elsewhere for various reasons. Between one and five of every 100 of these discards, on an average, will contain live trichinae. The feeding to swine of such scraps, as constituents of garbage or swill, constitutes a dependable, large-scale, year-round source of trichinae for swine. Garbage-fed swine have trichinae between three and five times as frequently as do grain-fed swine and hence are specially important as sources of human trichinosis. The garbage-feeding industry, as ordinarily carried on, is dangerous to the health of man and livestock, and often economically unsound.

Relation of Herpes Zoster to Chickenpox—During the last six years, among a daily average total of 2,050 patients there have been thirty-one cases of herpes zoster in the hospital with which Stern is connected, giving an annual incidence of 25 per thousand. The scars and history of a previous attack, five years and twenty-four years before, were found in two cases. The second attack in the first case was so slight that it would not in the ordinary way have come under medical observation, and that in the second case subsequently caused chickenpox in another patient. During these six years all cases of herpes zoster were referred to the author and have received special attention. Five persons were affected with chickenpox, in none of them could a possible source of infection be found, except that four had been in contact with herpes zoster. The approximate incubation periods were fifteen (twice), seventeen and nineteen days, respectively. The eruption of herpes zoster is caused by infection passing from the sensory ganglion down the course of the sensory nerve to the skin. Herpes zoster and chickenpox affect the same areas of skin with equal frequency.

Chronic Agranulocytosis Successfully Treated with Liver—Das Gupta and Wits state that a man who had suffered for five years from an unexplained iridocyclitis was discovered during the course of a routine investigation to have a mild chronic agranulocytosis. Sternal puncture revealed arrest of maturation of the myelocytes in the bone marrow. The patient had taken aminopyrine and gold in the past, but no clear evidence of sensitivity to either of these drugs was obtained. There was no response to pyrimidine nucleotides or to pentnucleotide, but on treatment with intramuscular liver extract the white cells returned to normal levels and the bone marrow was restored to normal. The blood has remained normal without further treatment, but the iridocyclitis has not improved greatly.

Oral Administration of Estrogen to Premature Babies—Since about September 1936 according to Potter, estrogen (progyon) has been used orally for premature infants at the Bristol Maternity Hospital. The dose found satisfactory was 500 international units twice daily. A double dose was dissolved in 2 drachms (8 cc.) of warm (not hot) water and 1 drachm (4 cc.) given as a dose. Since estrogen has been used, none of the eleven premature babies born at the hospital to whom it was administered have died. One sick infant, a boy, was benefited by the preparation. The baby weighed

7 pounds (3,175 Gm) at birth, was fed artificially, developed gastro-enteritis and his weight fell to 4 pounds 14 ounces (2,210 Gm) at two weeks. At this stage estrogen was added to the other treatment and the baby eventually did well, gaining half a pound (225 Gm) weekly and he weighed 12½ pounds (5,670 Gm) at 4½ months.

Weil's Disease in Brisbane—Johnson and his co-workers make a distinction between Weil's disease by restricting this term to the classic type caused by *Leptospira icterohaemorrhagiae* and use the inclusive term leptospirosis for the leptospiral infections generally. Three cases of classic Weil's disease occurring in Brisbane are reported, one of which was fatal. The first patient was a sewer worker who was infected in 1935. His illness was clinically typical, but pathologic confirmation of the diagnosis was not forthcoming at the time. Reinvestigation of the case seventeen months later showed that the patient's serum still contained, to a diagnostic titer, agglutinins against *Leptospira icterohaemorrhagiae*. The second patient, although he became ill and died in Brisbane, had left North Queensland, where leptospirosis is endemic, six days previously. Serologic reactions show that the infecting *Leptospira* was closely allied to, and probably identical with, the *Leptospira* of classic Weil's disease. The third patient was a sewer worker. His illness was typical, and the diagnosis was confirmed by the isolation of leptospirae from the blood and by their detection in the urine, as well as by agglutination tests. Both the first and the third patient became ill while working in the same sewer, but at an interval of seventeen months. In a series of eighty-five wild rats examined in Brisbane in 1936, two were found to be carriers of leptospirae. In a second series of 100 rats examined in March 1937, six were found to be carriers of leptospirae. The two strains of leptospirae isolated from rats in 1936 were found to correspond serologically with the Wynberg strain of *Leptospira icterohaemorrhagiae*. The human strain isolated, while in general similar to the other, showed some relationship also to an Andaman strain.

J Grossman L Adlersberg and I Telemann—p 621

Tuberculosis of Duodenum—Grossman and his associates give the history of a man aged 32 who was hospitalized on account of periumbilical pains nausea severe attacks of vomiting, anorexia and emaciation. The patient was subjected to a thorough examination to several tests and to a roentgenologic examination of the stomach. The condition was finally diagnosed as stenosis of the third portion of the duodenum. In the course of the operation to which the patient was subjected a transmesocolic superior gastrojejunal anastomosis was made. However, he died on the day following the operation. The authors describe the necropsy and the microscopic aspects of the tuberculous lesions. On the basis of their macroscopic and microscopic observations they give as the diagnosis ulcerous duodenal tuberculosis following probably tuberculosis of the mesenteric and retroperitoneal lymph nodes, produced by lymphogenic metastasis or by contiguity. The existence of a cicatrized and sclerotic pulmonary focus speaks against the direct production of the duodenal lesion, for the pulmonary focus, not being an open one the swallowing of infected sputum cannot be incriminated. The transmission by the blood stream must likewise be rejected because of the absence of foci in other visceral organs and the extension of the bacillary lesions in the immediate surroundings of the duodenum. After citing two possible modes of lymphatic transmission of duodenal tuberculosis the authors point out that in view of the fact that the bronchial lymph nodes are not involved the primary focus was probably not in the lung and that because of the intensity of the bacillary process in the region of the mesenteric lymph nodes the primary infection must have been in this region.

and M Lelong—p 700*New Rat Bite Fever A Lemierre J Reilly A Laporte and M
Morin—p 705

New Rat-Bite Fever—Lemierre and his associates call attention to a rat-bite fever that is distinct from sodoku. It is not a spirochetosis but a septicemia, the specific agent of which is a bacterium. They report the history of a man, aged 40, who was bitten by a rat on the dorsal surface of the right index finger. Four days later he had chills and attacks of vomiting and his temperature increased to 104 F. The febrile state persisted for a month and a half. The fever was of the intermittent quotidian type. The elevation of the temperature in the evening was usually preceded by chills and the nocturnal defervescence by profuse sweating. Several days after the onset of the disease, severe articular pains appeared which involved nearly all the joints but particularly the left elbow and wrist. A hydrarthrosis of the left knee supervened after a month, but it disappeared rapidly following a puncture. Moreover, almost from the beginning the patient complained of sore throat and painful swallowing. The diagnosis of sodoku which at first was thought of was abandoned in view of the clinical aspects, the negative results of the inoculations in mice and guinea-pigs and the failure of the arsphenamine treatment. Intravenous injections of sodium salicylate were likewise without effect. Two bacteriologic blood cultures were made one on the nineteenth, the other on the twenty-ninth day. The second disclosed in the aerobic milieu *Streptobacillus moniliformis* in pure culture. The authors review the literature about this micro-organism particularly the experimental studies conducted by Levaditi and his collaborators. Then after citing other cases of rat-bite fever from the literature they give their attention to the question of the frequency with which *Streptobacillus moniliformis* occurs in rats. They review studies conducted by Strange-

ways and describe their own investigation, which corroborated the results obtained by Strangeways, namely, that *Streptobacillus moniliformis* is a part of the buccopharyngeal bacterial flora of normal rats.

Brunerie and P Moutel—p 389

Methenamine in Treatment of Korsakoff's Psychoses—Brunerie and Moutel tried the intravenous injection of large doses of methenamine in patients with Korsakoff's psychosis. Their object was to counteract the polynephritic symptoms and to influence the liver. They report eight cases in which methenamine was administered intravenously by means of ampules of 10 cc, containing 0.25 or 0.5 of methenamine. The injections were given daily, their total number being twelve or twenty. As a result, the polynephritic symptoms were greatly improved, the enlarged liver decreased rapidly in size, the appetite increased, the diarrheas disappeared and, parallel with these improvements, a considerable amelioration in the mental disorder was observable.

*Otic Phenomenon as Precursory Sign of Measles M Bessaloff—
p 535

Otic Phenomenon as Precursory Sign of Measles—Bessaloff directs attention to an otic sign which he observed in a number of patients who later developed measles. When called to see a child with fever, he has made it a general practice to examine the ears carefully. In doing so he found that in those with latent measles, during the period of the invasion of the disease an otic phenomenon was observable, namely, redness of one or of both tympanic membranes. This redness persists without aggravation as long as does the febrile condition. During this period the author noted also, in nearly all cases, symptoms of nasopharyngeal catarrh. With the appearance of the exanthem, which coincides with the fall in the temperature the changes in the tympanic membrane lessens. A rose coloration remains for about twelve hours, then it disappears like the catarrhal symptoms. The author reports nine cases which illustrate the various stages of the phenomenon.

Morrou—p 980

Cardiac and Pulmonary Pains in Course of Splanchnicotomies—After outlining this method of sympathectomy Leriche describes two cases. The first patient undergoing splanchnicotomy under spinal anesthesia, complained of severe pain in the heart when the left splanchnic nerve was not yet completely cut. Following procaine hydrochloride infiltration the pain ceased immediately and the section could be completed. Several days later, in cutting the right splanchnic nerve of another patient, also under spinal anesthesia, the patient complained of severe pain in the right lung. Here again infiltration of the central end arrested the pain and the section could be completed without further complaint from the patient. In two other cases the section on the left side caused sudden cardiac pain. The author thinks that the fact that the pain appeared at the moment of resection indicates that it can have no other explanation than that it is the result of an excitation of the centripetal fibers, and the instantaneous results of the administration of procaine do not contradict this. From then on the author always resorted to infiltration before cutting even when the operation was performed under general anesthesia.

trying to explain these pains, he points out that one can hardly assume a direct connection or a simple centripetal phenomenon. The only plausible hypothesis is a vasoconstrictor reflex, which acts at the level of the heart and lung and elicits the pain. In view of the strict localization and unilaterality, an intermediate epinephrine effect cannot be assumed, since this would have produced more diffuse effects. One must therefore ask oneself whether normally the central termination of the great sympathetic may not produce sympathetic vasomotor phenomena. Evidently this has to be verified experimentally. But the author thinks that the facts must be accepted for the present. He shows further that they are of interest in connection with certain pathologic phenomena. He calls attention to the appearance of anginose crises in connection with meals. These are usually explained as the result of a mechanical action on the heart, of the compression of the diaphragm by a distended stomach, without thinking that the patient with angina pectoris eats little, that the stomach is filled from above and not from below up, and that the air filled pocket is hardly capable of counteracting the normal diaphragmatic tonicity. The author considers it more reasonable to assume a nervous phenomenon or a circulatory reflex. Moreover, if splanchnic excitation can have a pulmonary repercussion, it may be assumed also that the same excitation can be carried into the abdominal region.

Glycemia and Ketonemia Following Epinephrine Injections.—Andreis made determinations of the glycemia and ketonemia following an intramuscular injection of 0.3 mg. of a 1:1,000 solution of epinephrine in forty-five infants, both normal and suffering from certain diseases with or without involvement of the liver functions. As a control for the efficacy of epinephrine, the behavior of the leukocytes during the reaction was followed. The author found that glycemia, ketonemia and the leukocytes do not follow parallel curves. Oxibutyric acid increases more than preformed acetone and diacetic acid. The reaction of glycemia and ketonemia in normal infants is slight, reaches the peak within the first half hour following the injection, and returns to normal in an hour and a half. Acetonuria does not appear or, if it does, it is slight. The reaction is intense in infants who have ketonemia before the test, as well as in those suffering from nutritional disorders and diseases of the respiratory tract. Generally the peak of the reaction is reached in an hour or an hour and a half after the injection and then glycemia and ketonemia return to normal. Acetonuria, which is related to the intensity of the glycemic and ketonemic reaction, appears in most of the patients but not all who have a retarded intense reaction. The highest figure of ketonemia following an intramuscular injection of epinephrine in normal infants is 577 mg. per hundred cubic centimeters of blood. The total ketonemia and glycemia after injection of epinephrine in infants suffering from nutritional and respiratory diseases are, respectively, 31.19 and 0.32 mg. per hundred cubic centimeters of blood. The spontaneous ketonemia that is present in infants with a fasting stomach is not related to the function of the liver. The author concludes that the intense and prolonged increase of glycemia and ketonemia after an injection of epinephrine shows insufficiency of the liver and that the epinephrine test is of diagnostic value.

- *Roentgen Therapy of Inguinal Lymphogranuloma. C. Guarini—p. 335
Pick's Syndrome. Case. C. Mole—p. 339
Treatment of Grave Chronic Malaria. P. Corsonello—p. 343

Roentgen Treatment of Inguinal Lymphogranuloma.—Guarini advises repeated roentgen irradiations in small doses in the treatment of subacute inguinal lymphogranuloma. He gives the irradiations with a current of 180 kilovolts, 3 milliamperes, a focal distance of 40 centimeters and a filter of 5 mm. of lead and 2 mm. of aluminum, through fields of 10 by 15 cm.,

which receive one third of the erythema dose, that is, 250 or 300 roentgens, during each treatment. The irradiations are given at intervals of four or five days. The number of irradiations depends on the evolution of the disease when the roentgen treatment begins to be administered and the local reaction to the irradiations. As a rule from four to twelve complete the number of treatments. The most favorable results are obtained when the treatment is given early. The treatment is harmless and the disease is controlled more rapidly than with other treatments. The fear of the formation of a larger number of adhesions when the latter are already formed is not justified. The author has resorted to the treatment in eleven cases. Two patients discontinued the treatment. The remaining nine patients obtained complete cure of the disease, which has been verified several years after completion of the treatment.

Intraspinal Alcohol Treatment.—According to Spangenberg and his collaborators, the intraspinal injections of alcohol in the treatment of peripheral neuralgia are dangerous. The injected alcohol may cause muscular atrophy and degeneration of the cells, sphincter disturbances, impotence, muscular hypotony and difficulty in walking. The authors' statement is supported by the results of experiments and by those obtained in a group of seven patients. Microscopic studies of the spinal cord, spinal ganglions and nerve roots of rabbits which were given intraspinal injections of absolute alcohol showed processes of neurolysis, lymphocytic infiltration and degeneration of the nerve tissues. The patients were treated for sciatic neuralgia, obliterating arteritis with incipient gangrene, tabetic radiculitis and pleuropulmonary cancer. In all cases the alcohol injections were administered with the patient in the lateral position on the normal side, with the buttocks or the cephalic part of the thorax elevated, in relation to the thorax. The dose varies from 0.25 to 1 cc. of pure alcohol and is injected slowly. It may be repeated fifteen or twenty days after the first injection if necessary. In five cases the results of the treatment were transient, in one case the type and intensity of pain did not change and in one the treatment controlled pain definitely, as has been verified two years after discontinuation of the treatment. There were no complications in the case in which the pain was not modified. In the remaining six cases, disorders such as muscular atrophy and hypotony, impotence and sphincteric and ambulatory disturbances took place. The authors believe that intraspinal alcohol treatment may be resorted to only in case of inoperable cancer of the rectum, colon, prostate, testicle, uterus and lumbosacral column.

Value of Nephropexy.—Berri considers nephropexy of value in the treatment of renal ptosis when the operation follows definite indications, which are the presence of renal pain or of urinary disturbances. The diagnosis of renal ptosis is made by pyelography and excretion urography. Patients suffering from renal ptosis uncomplicated by renal pain or urinary disorders obtain satisfactory results from the use of an elastic abdominal belt without resorting to an operation. The failures of nephropexy depend on a defective technique, especially in fixing the kidney in a low situation, or using nonabsorbable suture material, or else on the presence of chronic appendicitis.

The coexistence of the latter points to the advisability of doing an appendectomy during nephropexy. The technic of Salleras for nephropexy gives the best results. It consists, in short, of making an incision from the tenth rib and the sacrolumbar tissues to the superior anterior iliac spine, freeing the kidney and upper part of the ureter from nearby adhesions of muscular and conjunctive tissues and then fixing the kidney in the proper situation. In cases of bilateral renal ptosis the operation is done only on the painful side. The author reports satisfactory results with the technic in twenty-two cases. In all cases the results of the operation, as to the correction of the position of the kidney, were verified by pyelography.

Cholesterol Metabolism in Glycogen Storage Disease

—Beumer reports the clinical history of a boy in whom glycogenosis was complicated by xanthomatosis. The cholesterol content of the serum was greatly increased and was not influenced by a diet with a high or with a greatly restricted cholesterol and fat content. The cutaneous manifestations and the hepatic swelling were not influenced during the three months period when the patient was on a diet that was free from cholesterol and from fat. From these observations the author concludes that the xanthomatosis, which existed in addition to the glycogenosis, was not dependent on alimentary influences but rather was caused by an endocrine disturbance in the cholesterol metabolism. This suggests that the hypercholesteremia existing in uncomplicated glycogenosis is likewise due to endocrine factors.

Determination of Time of Death—Mueller says that a practitioner, even though he may not need to give expert testimony on the question of how long a body has been dead, should at least know what factors deserve attention so that he may record them for future reference, should he be the first physician called to see the body. Discussing the inspection of the eyes, the author points out that Tonelli believes that during the first twenty-four hours after death the pupil can readily be deformed by pressing with the finger on the bulb, but that this is no longer possible if more time has elapsed. The condition of the cornea is more important for practical purposes. Twenty-four hours after death it begins to be turbid as the result of drying. However, if the eyes of the cadaver are open, this drying process will begin much earlier (about one and three quarters hours after death). It is therefore important that the physician report whether the eyes of the cadaver were open or closed. In cadavers that have been in the water, it should be remembered that light eyes may assume a brownish color (after twenty-four hours has elapsed). This is important not only for the determination of the time of death but also for the identification. The author questions the often repeated statement that the beard still grows after death, pointing out that this growth is only apparent and due to the fact that the turgor of the skin decreases, the hair becoming more prominent as a result. Further he discusses the death spots, which may appear at both sides of the neck thirty minutes after death. Such spots at the side of the neck are often erroneously regarded as pressure points and as an indication of strangling. The physician should try to determine whether these spots can be pressed away. If similar obliterated reddish spots appear gradually on other parts of the cadaver, the spots at the neck may be regarded as ordinary death spots. If strangling has actually taken place, subcutaneous hemorrhages result which cannot be pressed away. A mere hyperemia that may result from strangling disappears rapidly on the cadaver, even if it was quite noticeable during life. The death spots pale in response to pressure at first, but later (twenty-four hours or longer after death) they no longer do so. The behavior of the spots should be carefully tested in this respect. In examining the skin of

the patient, the hair may be found to stand up (goose flesh formation). This does not necessarily indicate that the person was greatly alarmed but may be the effect of cold to which the cadaver was exposed after death. The facial expression of the cadaver is of no importance, since the musculature relaxes after death. Rigor mortis may develop instantaneously, but this is rare. Usually it begins at the temporomaxillary joint, from one to two hours after death and progresses downward and it disappears again in the reverse order after from forty eight to sixty hours (depending on the outside temperature). Whereas the cooling of the skin of the cadaver is not sufficiently uniform to be of definite value, the cooling of the internal organs is slower and has more regularity. In this connection the author stresses the importance of measuring the rectal temperature.

*Significance of Cutaneous Manifestations in Acute Articular Rheumatism. E. Traub—p. 769

*Question of Hypersplenism. W. Schmidt—p. 790

Distribution of Salt and Water in Nursing—Kerpel-Fronius shows that the higher chloride, sodium and water contents as well as the lower protein, rest nitrogen and potassium contents of the muscles of new-born infants are the manifestation of a water distribution in the muscles which differs from that of adults. The total water content of the muscles for each gram of protein decreases considerably during the time of growth. This dehydration, however, does not signify a decrease in the water combination of the protein, for the quantity of the cell water per gram of protein remains practically constant. The dehydration of the muscles is exclusively at the expense of the interstitial water. The muscles of the new born have a water distribution much like that existing during edema in adults. The comparatively large amount of interstitial water in the organism of nurslings probably plays a part in the hydro liability of nurslings.

Cutaneous Manifestations in Acute Articular Rheumatism—Traub shows that the allergic factors which were discovered to play a part in acute articular rheumatism give new etiologic significance to symptoms accompanying it. By interpreting the local rheumatic manifestations as allergic hyperergic tissue reactions, it is no longer important whether rheumatism is an infectious disease by itself. According to Rossle, various organisms and different ports of entry may produce allergizing diseases, the decisive factor being the affinity of toxins to certain tissues. Considered from this point of view, rheumatism is similar to syphilis and tuberculosis, for these too are infectious, make the involved organism allergic and cause a complicated interrelation between hypersensitivity (hyperergy) and subsensitivity (immunity). In all these disorders the causal organism produces a primary lesion in some part of the organism and at the same time causes sensitization. This primary stage is followed by a secondary one, which in the case of rheumatism, as in tuberculosis and syphilis, is characterized by great sensitivity to toxins and a tendency to inflammations. In case of new attacks by the antigen, the already hyperergic organism reacts with general reactions and multiple local allergic-hyperergic inflammations. The similarity of rheumatism to syphilis and tuberculosis is demonstrated also by the appearance of cutaneous manifestations during the secondary stage. Annular erythema and rheumatic urticaria can be explained as toxic-allergic efflorescences, and nodose rheumatism as a peripheral hyperergic inflammation in a sensitized organism is symptomatologically and prognostically related to them. The author cites observations in several cases which prove that the peripheral manifestations accompanying similar clinical processes and that for this reason their relationship must be considered probable. Annular erythema, rheumatic urticaria and nodose rheumatism accompany a generalization of the

rheumatic infection and usually appear when the cardiac values, the nervous system or the serous membranes become involved. All three processes have common relations to fluctuations in the allergy of the organism and, as indicators of the generalization of the process, they have considerable prognostic significance.

Hypersplenism—Schmidt reports the histories of a girl, aged 10, and a boy, aged 14, both of whom had severe anemia with leukopenia and thrombopenia. Since the usual therapeutic methods failed to produce the desired effects, the enlarged spleens were removed. The splenectomy was followed by a noticeable improvement in the anemic condition and by an increase in the leukocytes and the platelets. The most noteworthy aspect of the two spleens was their size. In the girl it weighed 260 Gm, in the boy 950 Gm, when the normal weights would have been 70 and 85 Gm, respectively. After describing the histologic aspects of the extirpated spleens, the author cites Heilmeyer's report about patients in whom anemia was accompanied by splenic enlargement and by morphologic changes and reduced resistance in the erythrocytes. On the basis of these observations, Heilmeyer assumed the existence of a primary splenic disease for which blood destruction is characteristic and which he designates as hemolytic hypersplenism. The author points out that the two described cases cannot be identified with Heilmeyer's hemolytic hypersplenism, because neither the shape nor the resistance of the erythrocytes was changed and there were no signs of increased blood destruction in the spleen. Nevertheless he regards the disorders in the reported cases as hypersplenism, reasoning that if it did not produce anemia by destruction it might produce it by exerting an inhibiting effect on the blood formation in the bone marrow. He points out that Naegeli regards hypersplenism in this light by ascribing the inhibiting action to the endothelium of the splenic sinuses. Kretz is of the same opinion and M. B. Schmidt talks of a 'depressor hypersplenism'. The connection between spleen and bone marrow supposedly takes place by way of the blood stream, by means of a substance that is formed in the endothelium of the splenic sinuses. After pointing out that it is difficult to furnish the direct proof of such a function of the endothelium of the splenic sinuses, the author discusses whether the sinus hyperplasia in the second reported case was accompanied by an increased function. He reaches the conclusion that in this case the anemia probably was caused by the hyperplasia of the splenic sinuses, the favorable effect of the splenectomy as well as some literature reports seemingly justifying this conclusion, but he does not consider generalizations permissible, pointing out that the first case and other reports indicate the involvement of many other factors, some of which are still unknown.

Purpura with Hemophilia-like Disturbance in Coagulation—Tschopp's report is a contribution to the symptomatology of atypical diseases of the blood. He describes the history of a woman who has been under his observation for years. She presented the clinical aspects of purpura, which however, was complicated by a disturbance in the blood coagulation like that existing in hemophilia. Otherwise the blood was normal. In the course of time the retardation of the coagulation disappeared and the coagulation values became normal. On the basis of this history the symptoms of hemorrhagic diatheses and of hemophilia are discussed and especial attention is given to the question of hemophilia in women. This problem has not been definitely solved as yet. The author shows that the occurrence of hemophilia in women has not been definitely demonstrated nor can it be absolutely excluded. The case

reported in this paper can be classified in none of the known groups of hemorrhagic diathesis. It has been designated as purpura with temporary hemophilia-like disturbance in the coagulation, possibly as a temporary thrombomase deficiency of unknown origin.

Circulatory Complications of Diabetes Mellitus—Radnai and Weisz direct attention to the circulatory complications of diabetes mellitus. Their observations were made in 400 cases. Electrocardiographic tests were made in 260 of these and it was found that 40 per cent showed changes. Cardiac decompensation was discovered in 20 per cent, anginose conditions in 10 per cent, vascular changes of the fundus oculi in 30 per cent and peripheral arteriosclerosis in 8 per cent. It was observed that the electrocardiographic changes as well as the appearance of cardiac disorders is primarily dependent on the age of the patient and secondly on the height of the blood sugar. Insulin therapy or the quantity of insulin seems to be of no importance in the development of cardiac disorders. It was impossible to prove that diabetes mellitus is a causal factor in hypertension. The cardiac disturbances of diabetic patients are not caused by the hypertension that may exist but rather by the metabolic disorder that accelerates and increases the development of vascular changes. Besides the age of the patient it is chiefly the blood sugar value and the duration of the metabolic disorder that influence the development of cardiac disorders. The degenerative processes in the fundus oculi are the result of the metabolic disturbance. Their development too, aside from the age of the patient, is dependent chiefly on the height of the blood sugar and the glycosuria. The author emphasizes that a thorough clinical examination of a diabetic patient requires not only an examination of the urine and the blood but also an inspection of the retina and an electrocardiographic test. In case of pains in the extremities an oscilometric examination is necessary. Oscilometric changes and the appearance of symptoms of peripheral arteriosclerosis are dependent on the age of the patient and on the duration of the metabolic disorder. If the blood sugar is unusually high cardiac and retinal disturbances predominate but peripheral arteriosclerosis appears generally in those persons in whom the metabolic disorder is one of long standing but in whom the blood sugar is comparatively low so that insulin is given either in small doses or not at all.

Action on Blood Sugar of Various Anesthetics—In order to determine how anesthetics influence the sugar metabolism Atnan and Fenz studied the blood sugar curve before, during and after various types of anesthesia in nondiabetic and in diabetic patients. The types of anesthesia investigated were ether anesthesia, intravenous anesthesia and spinal anesthesia. It was found that the intravenously induced anesthesia influences the blood sugar only slightly so that it may be employed in diabetic patients without special precautions. In comparing the effects exerted on the blood sugar by spinal and ether anesthetics, the authors found that after spinal anesthesia the increase is much less than after ether anesthesia. However, the increase in the blood sugar lasted longer (from six to twenty-four hours) after spinal than after ether anesthesia. In a mild case of diabetes, the increase in blood sugar was less noticeable than in normal persons. The authors conclude that spinal anesthesia is not contraindicated in diabetes mellitus.

Aspect of Heterotopic Stimulus Formation—Bloch analyzes the electrocardiograms of two patients which demonstrate in what manner impulses of the same heterotopic stimulus may become manifest as extrasystoles as well as in the form of automatic beats. In the first case regular blockage of the

emissions of a rapid heterotopism led to slow automatism. If the impulses are emitted in their actual stimulus periodicity, there develop (if it takes place after an automatic beat) apparent extrasystoles or (if it is the period of a compulsory stimulus formation after a transmission beat) real extrasystoles. In the second case an automatic period is twice as long as the coupling (the period of compulsory stimulus formation) of neighboring extrasystoles, identical in form, which are bound to transmissions. The automatic period develops by emission blockage of a rapid heterotopism, the periodic length of which represents the coupling of the extrasystole. In both cases automatic and extrasystolic beats can be traced not only to a common stimulus former but also to a stimulus formation process of identical rhythm, which in case of regular emission blockage of its stimuli produces automatic beats, and in case of emission blockage produces extrasystoles.

Total Thyroidectomy in Cardiac and Vascular Diseases—Following a review of the literature, Singer reports the experiences with total thyroidectomy in cardiac and vascular diseases made at a Viennese hospital. He describes and discusses several cases of cardiac and vascular diseases in which thyroidectomy proved helpful and reaches the conclusion that it is indicated in cardiac defects and hypertension with chronic decompensation, in which digitalis or strophanthin have little or no effect. Especially suited for thyroidectomy are cases of refractory dyspnea, for of all the symptoms of decompensation dyspnea is most promptly counteracted by thyroidectomy. This explains the success of thyroidectomy in the cases of severe dyspneic emphysema. The operation is indicated also in refractory angina pectoris and finally in obliterating endarteritis. If the success of thyroidectomy is at least partly due to a reduction in the oxygen requirements, it is to be expected that those cases promise the best surgical results which have an increased basal metabolism before the intervention. The author advises that patients whose metabolism shows minus values should be excluded from total thyroidectomy. The lowest metabolic rate at which thyroidectomy was done at his hospital was plus 16. After pointing out that the operation probably exerts its favorable effect by relieving the circulation (through the reduction in the process of oxidation) and by thus enabling the circulatory organs to respond more readily to medicinal treatment, the author admits that the method still has certain defects, which are connected with the totality of the thyroidectomy. In order to exclude these, his clinic is now investigating to what extent the subtotal resection of the thyroid might produce the same therapeutic effects without resulting in the slight myxedematous complications. That these complications are slight is proved by the fact that at the author's clinic it has never been necessary to administer thyroid preparations. To be sure, in some of the thyroidectomized patients mild myxedematous symptoms appeared, such as swelling of the lids, dry exfoliating skin and falling out of the hair. However, these manifestations usually disappeared again spontaneously after one or two months.

Malarial Therapy in Progressive Muscular Dystrophy

—After reviewing a previous report on malarial therapy of progressive muscular dystrophy in which he had demonstrated that, at the onset and during progressive exacerbations of the dystrophy, malarial therapy promises favorable results whereas in late cases it may arrest the disease process and induce a favorable general condition, Rottmann describes his studies on the histologic changes produced by the malarial therapy. He says that it was tried in muscular dystrophy because of its activating effect on the defense powers of the organism. He reports histologic studies in three cases in three different stages. The histologic studies on the skin were made before and after the

therapy. They reveal an anatomic regression of the chronic infiltrative process and are a further proof that vaccination malaria exerts a specific action on the tissues.

Value of Electrocardiogram During Diphtheria

Szczeklik states that the electrocardiogram during the course of diphtheria has been of great value for the estimation of the condition of the heart muscle. He has taken electrocardiograms of sixty patients forty children ranging in age from 6 months to 10 years, and twenty adults. Antitoxin had been administered and general treatment instituted in all cases. Five lethal cases from heart failure showed, at necropsy, degenerative changes of the heart muscle. The changes which have been observed in the electrocardiogram could be divided into two groups: disorders of the heart muscle and disorders of the circulation. In conclusion he says that 1 Diphtheria may cause damage to the heart muscle and the conduction system, as well as to the irrigation system, the damage being mostly done to the muscle. The damage to the irrigation system is rarer and usually complicated with damage to the conduction system of the heart muscle. 2 The changes in the electrocardiogram showing heart muscle damage may appear on the third day of the disease. The histopathologic changes of the heart in fatal cases are often those of degeneration of the muscle, and more rarely those due to blood extravasation and hypotaxis. The latter may appear on the eighth day of the disease and was observed in one case of the series. 3 In lethal outcome during the course of toxemic diphtheria attributed to the heart itself there were found some typical changes in the electrocardiogram and, histopathologically, in the system of heart conduction. Changes in the heart muscle itself as the cause of death have been found to be rarer. 4 The electrocardiographic changes observed consisted of tachycardia, slowing of circulation and arrhythmia, and even extrasystolic arrhythmia, which, however, do not always result in death.

Allergy and Changes in Blood Vessels—Ehrström says that experimental and clinical investigations during recent years seem to show that the blood vessel changes in diffuse glomerulonephritis, periarthritis nodosa and rheumatic arteritis represent different forms of allergic manifestations in immunization processes in the organism. The fact that allergic factors have been demonstrated on the occurrence of blood vessel changes in malignant hypertonia, eclampsia of pregnancy and atypical verrucous endocarditis indicates how unlike the anatomopathologic and clinical picture may be, depending on the course of the allergic reaction. In glomerulonephritis, periarthritis nodosa and rheumatic arteritis, in which the allergic reaction leads to irreversible changes, bacterial products, mostly from hemolytic streptococci, act as the antigen. In the literature, cases of periarthritis nodosa on an allergic basis are mentioned in which the antigen was of nonbacterial kind (among other things pollen). The author describes a case of allergy to foodstuffs in which administration of the antigen—cheese milk and eggs—caused violent shock, followed by fever, symptoms, from the joints and kidneys and bilateral pleuritis.

CERTAIN SIGNIFICANT ASPECTS OF CHILDHOOD TUBERCULOSIS

CHAIRMAN'S ADDRESS

RALPH M TYSON, M D
PHILADELPHIA

No other communicable disease equals tuberculosis in the taking of human lives. It probably exceeds all other diseases in individual and social importance, not so much from what it does to the child during the first infection but because of what it means to that individual during and after adolescence, when reinfection occurs. In a paper such as this it is impossible to consider all the many problems of childhood tuberculosis. A few of these problems will be discussed. The pathology of a first infection and the source of most reinfections are more clearly understood now than ever before. Just what constitutes resistance to the infection and how an individual develops immunity are controversial subjects at present. Early diagnostic signs are very indefinite and frequently missed, until there is evidence of extension of the disease. Much has been accomplished with regard to the cure of the disease, but more needs to be done along the line of prevention. Special attention needs to be given to preventing reinfections. It is because of these significant aspects of tuberculosis that I have selected this subject for my address as chairman of the Section on Pediatrics. I do so without any claim for original work or ideas regarding tuberculosis. It is merely an attempt to summarize the ideas of others and to emphasize these few particular phases of the condition. I want to stress especially the need for a more general use of the tuberculin test in order that the first infection cases can be found and the patient guarded against reinfection. A survey of the pediatric cases admitted to our children's ward during the past five years shows an incidence of positive Mantoux tests of 20 per cent.

EARLY PATHOLOGY

At the present time it is believed that most tuberculous infections are air borne and gain entrance into the human body by way of the pulmonary structures. Pasteurization and boiling of milk have practically eliminated the gastro-intestinal tract as a portal of entry.

After the tubercle bacilli are inhaled, they usually lodge in that part of the respiratory tract which is free from cilia, that is, the terminal bronchioles and alveoli. These organisms act very similarly to particles of dust and are, to a large extent, inert foreign substances which fail to produce any obvious clinical signs or symptoms.

However, according to Fried, the respiratory epithelium of these areas so involved responds within a very few minutes. The response is a change in the epithelial cells and is essentially an intra-alveolar lesion. Some of the tubercle bacilli remain entrapped exclusively within the intra-alveolar lesions. Others of these organisms, however, are carried by phagocytic cells through the walls of the air sacs, along lymphatic channels, and usually lodge in the regionally located lymph nodes. Undoubtedly in some cases the organisms are immured for life in these various areas of the lung tissue.

The size of the dose of the infecting organisms and the multiplicity of its repetition and the amount of the local tissue resistance are all determining factors in the spread of the disease. Wherever the organisms lodge they form the typical miliary tubercles and may proceed through the several stages of fibrosis, calcification or dissemination. Because in the young child the lymph channels are almost completely uninterrupted, tubercle bacilli are more apt to pass rapidly toward regional and distant lymph nodes. The lymph nodes themselves in the young child are poor filters, hence some of the organisms pass through them and may eventually reach the blood stream for generalized distribution of the infection. The less pervious pulmonary lymphatic system of the adult causes arrest of the bacilli out in the lung and the tuberculous focus develops at the point of this arrest.

This early pathologic condition is commonly spoken of as a primary complex and consists of the area of first penetration of the pulmonary structures, the lymphangitis along the pathways, and the lymph adenitis. The dissolution of the lipoid capsule of the tubercle bacillus permits of the liberation of tuberculo-protein. It is with the liberation of this substance that the tissues of the patient are sensitized and clinical symptoms are more apt to be recognized. Positive tuberculin tests may be secured at the end of this period, which may have lasted from three to six weeks. This early pathologic condition constitutes the first chapter in the life history of the organism in the human body and is frequently spoken of as a tuberculous infection rather than a tuberculous disease. The distinction is hardly justifiable. The time between the primary and reinfection types of tuberculosis may extend from a few months to many years. Usually the first chapter in this history ends with securing a positive tuberculin test, without palpably evident clinical, pathologic or x-ray changes. Clinical signs are most indefinite during this period.

One of the most animated controversies in tuberculosis work has been over the origin of reinfection, whether endogenous or exogenous in nature. A post-primary clinical tuberculosis constitutes the second chapter in the history of the disease. During this stage there is usually definite clinical, pathologic and x-ray evidence of reinfection and expansion. Evidence is

accumulating which seems to show that reinfections are the result of an exacerbation of a primary infection caused by the rupture of a lymph node or parenchymal tubercle into a new lymph node, a bronchus, the blood or lymph streams. Such endogenous reinfections resulting from softening of caseous nodules, the enormous reproduction of bacilli in the several forms of their development, and their subsequent rupture, have been emphasized by Long as the key problem in tuberculosis.

The best known stage of tuberculosis represents the third chapter in its life history. This is the very active stage of the disease and most often occurs when the child is no longer a child. It is known to exist in the very young infant and may involve nearly any organ of the body.

RESISTANCE AND IMMUNITY

What happens to the young child infected for the first time by the tubercle bacillus depends on a number of factors. Very probably the greatest of all is the degree of natural immunity of the child's own tissues first involved. The degree of acquired immunity which the localization sets up and the amount of allergic tissue hypersusceptibility resulting from this first localization are important points.

The relatively higher incidence of deaths from tuberculosis among young infants than in following age groups has given rise to the idea that babies resist the disease more poorly than older children and adults do. There is some question about the interpretation of that statement. A small infant has less opportunity of evading repeated and massive doses of living bacilli than does the older child and adult. Very probably it is the repetition of infections of young infants that has much to do with their supposedly increased susceptibility to the organisms. Their uninterrupted lymphatic channels permit a wider spread of tubercle bacilli. The more massive and widespread the dose received by the infant, the greater the amount of tuberculo-protein liberated when the bacilli disintegrate.

One cannot, however, entirely eliminate the influence of personal and public hygiene on the effects of tuberculosis. It has been known that native Indians, Negroes, the epileptic and the schizophrenic seem to be more susceptible to tuberculosis than other individuals. The question as to whether it is racial and connected with certain genetic properties or a matter of poor personal hygiene is not definitely proved. Undoubtedly poor hygiene plays a very important part in resistance to the tubercle bacillus. Resistance, however, is something which no one can estimate with any definiteness, and yet the degree of resistance to tuberculous toxins determines in a large measure the result of treatment. Whether the resistance of some patients and the lack of resistance of other patients is due to the quality of certain tissue cells and fluids on the one hand, or to the lack of these certain qualities, on the other, is a matter that is difficult to state. There is no doubt that there is a specific resistance to tuberculosis and no two children have this quality in the same degree.

The question of whether the primary infection is an asset or a liability is contested very earnestly by several groups of workers. Those who feel that it is an asset lean toward the belief that the use of the BCG vaccine is justifiable. Several of these investigators with cows, calves, guinea-pigs and rabbits state that those animals which have been given the vaccine and after a certain length of time are given virulent doses

of tubercle bacilli have certain resistance to throw off the reinfection, provided they develop a positive tuberculin test, while those animals which have a negative tuberculin test and are given virulent tubercle bacilli usually die within sixty days. Stewart, Myers and others believe that a negative Mantoux test is superior to a positive reaction from the standpoint of resistance to infection. They believe that any nonallergic, uncontaminated person occupies a more advantageous position than is possessed by an allergic person, so far as future experiences with the tubercle bacilli are concerned.

EARLY DIAGNOSTIC SIGNS

It is the hope of all who deal with children that a diagnosis of tuberculosis might be made during the first chapter of the life history of the tubercle bacillus. It has only been recently that these early diagnoses have been made as emphasized by Wallgren. Because of the importance of this particular phase of our problem, it seems well to have a definite diagnostic plan that will lead us to proper conclusions.

Exposure—A history of exposure and the finding of an active tuberculous lesion in a parent or other individual who comes in contact with children makes the problem a simple one. Such a history is not always available, however, and other means must be used.

Weight Curve—The weight curve of the child is not always a reliable guide. This is especially true of the small infant. It has been the experience of many to see a young infant with an active tuberculous infection continue to gain in weight during the early part of that condition. Due consideration must be given to stationary or perhaps loss of weight without any obvious cause.

General Condition—A change in the general condition of the child, with the appearance of such indefinite symptoms as irritability, fretfulness, fatigue and lack of appetite, are helpful diagnostic points. It must be remembered, however, that these symptoms may be due to many other causes.

Fever—Elevation of temperature, while not specific by any means, should always be regarded with suspicion. So far as is known at present there is no specific temperature curve associated with tuberculosis. When no adequate cause for the elevation of temperature can be elicited by careful physical examination, suspicion should always be directed toward the possibility of tuberculosis.

Later Signs—When a tuberculous infection has gone through the first chapter and reinfections have occurred, with resulting increase in toxemia, there are sometimes left indefinite but helpful diagnostic marks on the child. I refer particularly to the rather lusterless eye, the heavy long eyelashes, pouty lips, dry skin and hair, and hypertrichosis. These changes are evidence of toxemia of the disease.

Tuberculin Tests—Tuberculin tests should be made in all suspected cases, particularly if one or more of the aforementioned circumstances exists. The intradermal or Mantoux test, beginning with 1:10,000 dilution and repeating with ascending doses, will show allergic response within three to six weeks after the primary infection has occurred. It has been the experience of most physicians that this is an extremely valuable test and perhaps should be performed on all children who come under our care.

Serial X-Ray Studies—Serial x-ray studies of the chest have helped greatly from the diagnostic standpoint and are of far more value than a single x-ray

study Such diagnostic aid should be used whenever positive skin tests are obtained It is very difficult for the roentgenologist to tell positively whether the shadows found on a film of a certain infant's chest are due to tuberculosis or to some other pulmonary infection

Gastric Lavage—Comment is frequently heard as to the inability of small infants to raise sputum into the mouth Most of the time it reaches only the pharynx and is immediately swallowed If gastric lavage is done the first thing in the morning and careful study made of sediment so secured, tubercle bacilli in the positive cases are fairly frequently found Such laboratory evidence may be found even in the early cases Similar studies made on the stools of infants will occasionally reveal the organisms

Sedimentation Index—The sedimentation index of the blood tells us that an infection is present but does not particularly indicate tuberculosis It probably gives an idea as to the degree of activity of the infection

Skin Rashes—The appearance of erythema nodosum on the extremities and back of a young child should always arouse suspicion of tuberculosis While not appearing in all cases, it is recognized in a certain percentage Erythema nodosum may be caused by a number of other conditions

PREVENTION

The most efficacious procedure in preventing tuberculosis in infants and children is to keep them from coming in contact with open cases of the disease This appeals as the most logical method at our command today The so-called healed adult case may be a source of contamination It seems particularly valuable to prevent children from being born of tuberculous parents Neither man nor woman has a right to marry when actively ill with the disease, because under such circumstances children born of such parents usually have to live with them and constant exposure results Under such circumstances the securing of a healthy foster mother to care for the child in her own home will help to prevent contamination of the infant The tuberculous mother should not nurse her baby, and all close contact with the child should be avoided

The work with the BCG vaccine and reports so far available indicate the possibility that the prevention of tuberculosis by this method is probably desirable when one or the other of the parents has the disease In the present state of our knowledge it does not seem wise to recommend that this vaccine be used as a routine for all children, regardless of whether there is tuberculosis in the home or not The BCG vaccine does sensitize tissue and renders the child allergic to further contact with the tuberculo-protein It also causes a body to harbor living tubercle bacilli which may later on in life become active and virulent There are not sufficient data at the present time to determine the validity of this last statement

Tuberculosis developing as a result of the use of infected milk is becoming more rare The inspection and tuberculin testing of dairy cattle and the pasteurizing or boiling of all milk have done much to prevent the spread of bovine tuberculosis

Certain diseases have been accused of lowering the resistance of the child to such an extent that such children are more apt to develop tuberculosis or, if

they have it, to have reinfections occur Whether there is any specific relationship of measles, whooping cough and other diseases to the lessened resistance of children to tuberculosis or not has not been definitely shown It might be stated that the prevention of these diseases would help in preserving the natural resistance of the child

It seems that the full elimination of tuberculosis will depend to a large extent on finding out the ones that are already infected Active physical examination of all children attending school must become universal if such a hope is to be realized This examination in most instances will fail to show definite signs of early tuberculosis in the child's chest, so it will be necessary to include the tuberculin testing of all school children and serial x-ray studies of their chests for all positive reactors

A study of mortality records shows the increasing death rate from tuberculosis in children during adolescence and shortly thereafter The study also shows the increasing number of girls so infected During this time a great many children are anemic and underfed and going through changes in their endocrine glands and constantly being stimulated to a great variety of activities, thereby interfering with adequate rest There would appear to be some relationship between the development of the sexual functions and resistance to tuberculosis Animal experimentation seems to corroborate this idea In animals it seems that the removal of the gonads increases resistance to the disease

The greatest danger of tuberculosis in the weak, anemic or underfed child comes with the approach of and during adolescence Preventive work in this group is particularly deficient Long hours in badly ventilated class rooms and college lecture halls, and in stores and work rooms, together with a lack of recreation, irregular meals of poor quality and insufficient quantity and insanitary living in general are mainly responsible for the spread of tuberculosis in the adolescent The pediatrician might do well if he extended the age limit of his patients to include adolescents rather than the arbitrary twelve year limit

It was hoped, when it was discovered that vitamin D increased calcification in the body if given in therapeutic doses, that it might be used in aiding the body to calcify and thereby heal tuberculous infections There are not sufficient data at the present time to decide whether such a circumstance does happen Recent studies of vitamin C show that apparently an individual who has tuberculosis needs and retains more vitamin C in his body than an uninfected person Reasoning the other way, it might be stated that adequate amounts of vitamin C should be a part of every person's dietary

Infant feeding has become pretty well established, so that the dietary needs of children are better understood today than ever before The influence of maintaining optimum nutrition for every child, hoping thereby to increase resistance not only to tuberculosis but to all diseases, is a form of prevention that is frequently overlooked To secure optimum nutrition, good hygiene with adequate fresh air and sunshine is necessary The particular value of adequate rest is frequently overlooked in our care of children It is difficult to restrict activities of the growing child, but undoubtedly sufficient rest for each individual child will help materially in the prevention of tuberculosis

255 South Seventeenth Street

THE DEGREE AND PREVALENCE OF VITAMIN A DEFICIENCY IN ADULTS

WITH A NOTE ON ITS EXPERIMENTAL PRODUCTION IN HUMAN BEINGS

HAROLD JEGHERS, M.D.

BOSTON

The changing status of the vitamin deficiencies in this country is well shown by recent publications¹ emphasizing the rarity of the fully developed, classic diseases and the frequency of the milder deficiencies. This is particularly true with regard to vitamin A deficiency. In a preliminary report, the present knowledge concerning the biochemical and physiologic aspects of vitamin A, the clinical and pathologic aspects of vitamin A deficiency, the mechanism of night blindness and methods of detecting mild degrees of deficiency were reviewed.² The present study deals chiefly with personal observations, and reference will be made to but a few pertinent papers. Complete bibliographies are available elsewhere.³

PROCEDURE

The material forming the major portion of this paper was obtained from a study of the students of Boston University School of Medicine. Each student received a test on the biophotometer,⁵ and those with very low readings were rechecked before receiving therapy or else the result was confirmed with Edmund's test charts and photometric glasses. All tests on the biophotometer were performed in a dark room. The technic described by Jeans and his associates was followed.⁴ Each student received ten minutes' dark adaptation as a control, three minutes' exposure to bright light and ten minutes' additional dark adaptation, with five readings taken at two and one-half minute intervals. Edmund's test⁶ was done in a specially prepared room with black walls.

One hundred and sixty-two students were tested. The entire freshman class of sixty students was studied as a required exercise in biochemistry and physiology. The rest were selected at random from the remaining classes. Eleven students were eliminated because they had been taking concentrates of vitamin A. An elaborate dietary and general history was obtained from each subject and careful search made for objective and subjective manifestations of vitamin A deficiency. The fifty-five students found to have subnormal dark adaptation were treated and the results observed.

Aided by a Grant from the Robert Dawson Evans Memorial Massachusetts Memorial Hospital.

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

From the Fifth (Boston University) Medical Service, Boston City Hospital, and the Department of Medicine, Boston University School of Medicine.

Read before the Section on Practice of Medicine at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.

5 The material for Edmund's test was obtained by communicating with Dr. Carsten Edmund, Copenhagen, Denmark.

RESULTS

What constitutes normal dark adaptation is at present not entirely settled. Rather than say that one photometer reading represented vitamin A deficiency and another showed its absence, an entirely new approach was made to the problem. The fifty students showing the best dark adaptation were compared with the fifty students showing the poorest. Those with values falling in between these two groups were eliminated from the final analysis. For convenience of discussion in this paper the two groups will henceforth be called the normal and the subnormal group, respectively.

The dark adaptation curves obtained for the fifty normal subjects all fell within the limits of the shaded area, as shown in chart 1. The dark adaptation curves obtained for twenty-five of the fifty subnormal subjects

Chart 1—The twenty-five lowest dark adaptation curves. The other twenty-five low curves ranged between these and normal values. The fifty highest curves all fell within the shaded area.

are individually plotted in chart 1. Only the lowest curves are given. The twenty-five not shown ranged in value between these and the normal curves.

General information concerning the two groups is shown in table 1. There were forty-five men and five women in the subnormal group, essentially the same distribution as that in the normal group. Seventy-four per cent of the normal students ate at home, while only 16 per cent ate in restaurants and 10 per cent cooked meals in their living quarters. There was a noticeable difference in the subnormal group, the majority eating away from home, 32 per cent frequenting restaurants and 26 per cent cooking in their living quarters. Of this group, only 42 per cent lived and ate at home. The normal students who ate in restaurants spent \$7 a week per person, in contrast to \$5.50 spent by the subnormal group. The normal students who cooked in their living quarters spent an average of \$4.20 per week, in contrast to only \$2.80 spent by the deficient group.

A meal was considered complete when it included all the items commonly served. For example, doughnuts and coffee or rolls and coffee were not considered a complete breakfast. A sandwich and soda or sandwich and coffee were not considered an adequate noon meal. In the normal group, 32 per cent received three full meals daily and 68 per cent received two complete meals. Lunch in this group was the weak meal, but it was commonly brought from home and proved to be more substantial and varied than the sandwiches purchased in neighborhood lunch rooms by the subnormal group. No person in the normal group received less than two adequate meals daily. In striking contrast, 60 per cent of the subnormal group ate but one substantial meal daily. These students invariably had coffee with toast, rolls or doughnuts for breakfast, a sandwich or two for lunch at noon and a complete meal at night. Thirty-six per cent had two complete meals and only 4 per cent had three adequate meals.

The clinical data are summarized in table 2. The average number of colds per year in the two groups was two and one-tenth and two and two-tenths, essentially the same. However, in the normal subjects the colds lasted five and one-half days on an average, as contrasted to seven and four-tenths days for the subnormal subjects. Eleven of the normal group were sick in bed for an average of four and three-tenths days. The sicknesses included common colds, grip and one case of streptococcic sore throat. In the subnormal group, sixteen were sick in bed for an average of eight and five-tenths days, and the illnesses were distinctly more serious, including, besides common colds and grip, four cases of streptococcic sore throat, two of sinusitis, one of otitis media and one of colitis. In several of these cases the diet was adequate and the infections were probably responsible for producing the vitamin A deficiency. Thirteen of the normal group had chronic focalized infections, which were, however, all mild and included pyorrhea, dental abscesses, catarrhal postnasal drip, granular pharyngitis and, in one case, tonsillitis. The nineteen subnormal subjects with chronic infections, on the other hand, had more serious conditions, which included two cases of repeated furunculosis, one of chronic otitis media, two of colitis, three of purulent sinusitis and two of tonsillitis.

Evidence of specific manifestations of vitamin A deficiency proved to be most instructive. In the normal group, no one complained of night blindness. One student, with a severe refractive error, had photophobia, which, however, showed no change with vitamin A therapy. Two students (men) had mild dryness of the skin, probably unrelated to deficiency disease.

In marked contrast were the manifestations of vitamin A deficiency in the fifty students with subnormal dark adaptation. Twenty-seven were clinically aware that they adapted poorly in the dark, in other words, they had definite night blindness sufficient to be recognized without resorting to a photometer test. They noticed it particularly while driving an automobile at night, on entering a darkened theater, while observing fluoroscopic examinations, while trying to play golf at dusk and because of inability to recognize friends on the street in a dim light.

It is not generally appreciated that persons with night blindness may find it hard to adapt to bright illumination as well as to dim illumination. This causes photophobia and was present to some degree in fifteen of the subnormal group.

Three students showed dryness (xerosis) of the conjunctivae, especially when the eyelids were held open

for a minute or two. It was so mild as to be readily overlooked unless specifically kept in mind. Examination should be with oblique illumination. This observation was considered most important. All textbooks stress xerophthalmia as a leading sign of the deficiency. Actually, mild xerosis cannot be photographed. The illustrations usually shown in textbooks are reproductions of Bitot's spots and severe xerophthalmia, which have the appearance of frost on a window pane. This condition represents not simple dryness but opacity, thickening and keratinization of the conjunctivae. It was not seen in any case of deficiency studied to date and, judging by reports in the literature, must be very rare in adults in this country. The three students with

TABLE 1—*Eating Habits of Fifty Persons with Normal Dark Adaptation Contrasted with Those of Fifty Persons with Subnormal Dark Adaptation*

	Normal Group	Subnormal Group
Men	45 90%	44 88%
Women	5 10%	6 12%
Persons eating at home	37 74%	21 42%
Persons eating at restaurants	8 16%	16 32%
Persons cooking and eating in living quarters	5 10%	13 26%
Average weekly amount spent by persons eating in restaurants	\$7 00	\$5 50
Average weekly amount spent by persons cooking and eating in living quarters	\$4 20	\$2 80
Persons eating three complete meals daily	16 32%	2 4%
Persons eating two complete meals daily	34 68%	18 36%
Persons eating one complete meal daily	0 0%	30 60%

TABLE 2—*Clinical Data on Fifty Persons with Normal Dark Adaptation Contrasted with Data on Fifty Persons with Subnormal Dark Adaptation*

	Normal Group	Subnormal Group
Average number of colds per year	2.1	2.2
Average duration of each cold	5.5 days	7.4 days
Persons sick in bed during preceding year	11	16
Average period in bed per sickness	4.3 days	8.5 days
Persons with		
Focalized chronic infection	13	19
Subjective night blindness	0	27
Photophobia	1	16
Dryness of conjunctivae	0	3
Burning of eyes	0	3
Blepharitis	0	2
Dryness of skin	2	15
Hyperkeratosis follicularis	0	2
Itching of skin	0	3
Acne	2	2
Average international units of vitamin A obtained daily from food eaten	5,500	2,445

dryness of the conjunctivae complained of burning sensations of the eyes. Two had noticeable blepharitis, and the lids were edematous.

Fifteen of the subnormal group had dryness of the skin which was generalized and occasionally rough. In a few cases it was very annoying, and much cream and lotion was used in an attempt to soften the skin. Six students noted that the dryness disappeared each summer while they were home and ate adequately, only to reappear again a few months after their return to school. In three cases, generalized itching was troublesome. Two students had noticeable hyperkeratosis of the hair follicles.

The following case histories are given to illustrate examples of the severe, moderate and mild deficiencies of vitamin A.

CASE 1—A third year medical student, aged 25, while regularly testing members of his class was found to be night blind. There had been no serious illness since childhood. At the age of 19, while in college, he began to notice a progressive difficulty in driving an automobile at night. The glare of headlights was dazzling, and the road edge pedestrians and signs

were barely seen. After an accident he had his eyes examined. No pathologic condition could be demonstrated, visual acuity was normal, and his trouble was diagnosed as eyestrain from studying. After a month's vacation, night driving was resumed. Shortly afterward he injured a pedestrian and gave up night driving but continued to drive extensively during the daytime. Another feature of interest was his inability to play golf in the early evening although his friends could readily do so.

TABLE 3—International Units of Vitamin A per Ounce of Food*

Food	Reported Values	Average Values Assumed for Convenience of Calculation
Bread and cereals		
Cereals	0-40	20
Whole wheat bread	?	50
White bread	0	0
Yellow corn meal	198-236	200
Macaroni	0	0
Rice	?	10
Rye bread	0	0
Meats		
Pork (lean salt)	0	0
Average lean meat	?	5
Liver	2,860-3,920	3,000
Kidneys	210-323	250
Bacon	7	5
Fish

Oranges	26-108	100
Peaches	2-392	200
Pears	5	5
Prunes	770-800	800
Watermelon	35-39	35
Dairy products		
Butter (per pat)	50-500	100
Cheese	42-1,960	1,000
Cream	294	300
Fresh milk	31-98	50
Evaporated milk	196	200
Lard	0-2	0
Eggs	770-1,100	1,000
Vegetables		
Broccoli	176	200
Brussels sprouts	118-133	100
Cabbage	14-24	20
Carrots (raw)	940-2,630	1,000
Cauliflower	19-21	20
Celery (white)	0-6	5
Asparagus	50-275	150
String beans	140-392	200
Navy beans	21	20
Lima beans	0	0
Beets	0-7	5
Lettuce	49-1,960	500
Onions	0	0
Peas	245-392	200
Green peppers	245-398	300
Turnips	7	5
Yellow potatoes	119-1,960	500
White potatoes	10-14	10
Sauerkraut	7	5
Squash	780	700
Tomatoes	237-590	400
Spinach	2,500-9,800	3,000
Olive oil	14	10
Cottonseed oil	6-39	25

* These values were obtained from Eddy, Walter H. and Dalldorf, Gilbert. The Avitaminoses, Baltimore, Williams & Wilkins Company, 1937, and are reproduced by permission. The average values were assumed for convenience in calculating the vitamin A content of the 100 diets studied for this paper.

When he entered a darkened theater, it was necessary for the usher or a friend to lead him to a seat. Otherwise, from ten to fifteen minutes' adaptation was required before he could find his way down the aisle. Bright lights were as annoying as his inability to see well in dim light. In two further examinations the eyes were reported as normal. The student finally decided that it was normal for him to adapt poorly in the dark and ceased further quest for medical aid.

His general health remained fair. Accompanying the night blindness there had been progressively increasing dryness of the skin. About one year before he had noticed for the first time roughness of the skin due to enlarged hair follicles, more

marked on his back and on the extensor surfaces of his extremities. This persisted but did not increase. Examination revealed a dry scalp and dry skin, with moderate hyperkeratosis follicularis. The conjunctivae showed mild dryness (xerosis) but no Bitot's spots. There was definite blepharitis.

The results of the initial and follow-up photometer tests are shown in chart 2. The diet was of interest. Since leaving home seven years before, he had constantly observed the following regimen. Breakfast consisted of black coffee and doughnuts. Two meat sandwiches, coffee and dessert constituted lunch. Dinner consisted of meat, white bread, white potatoes, dessert, coffee and a small portion of vegetable. One pat of butter was taken with the evening meal. No milk, fruit, spinach, carrots, ice cream, liver or cheese had been eaten for years. The evening vegetable was either string beans, lima beans, beets, peas or corn. This choice was one of habit and not of financial necessity. The diet was calculated to supply less than 1,000 units of vitamin A daily. Treatment consisted of the administration of 25,000 units of vitamin A daily in the form of halibut liver oil concentrates and the addition of milk, butter, fresh fruits and vegetables to the diet. Remarkable changes followed. Subjective improvement in the night blindness was noted within ten days. After five weeks the skin had returned to normal texture. There was a feeling of general well being that had not been experienced for years. Within two months dark adaptation was entirely normal. The subject could now drive at night with ease, walk into a theater and find his way to a seat at once, and for the first time appreciate a fluoroscopic examination.

This case represents the classic fully developed picture of vitamin A deficiency. One senior had a practically identical story. This degree of deficiency was seen also in a girl college student aged 17 (trying to reduce), an accountant aged 31, a housewife aged 29 (trying to reduce) and a welfare worker aged 30. All these persons made a similar recovery.

CASE 2—A senior student, aged 27, was first observed during a routine test. Dark adaptation was moderately poor. He rarely drove at night because of the glare of headlights and his inability to see the road. On entering a theater he had to wait several minutes before attempting to find a seat. No detail could be seen during a fluoroscopic examination unless from twenty to thirty minutes was allowed for adaptation. There was moderate dryness of the skin but no hyperkeratosis. Xerosis of the conjunctivae was absent. These symptoms had been noted for several years. The dietary history was illuminating. Breakfast consisted of coffee and pie, lunch, of coffee and sandwiches. The patient ate his dinner at home. There were many idiosyncrasies in connection with food. Tomatoes once a week and apples were the only source of carotene. No milk, butter or cheese was taken. One egg a week and a serving of liver a month were eaten. Bread, meat and spaghetti constituted the bulk of the food consumed. This diet was estimated to supply about 1,300 international units of vitamin A daily.

The initial and follow-up photometer tests are shown in chart 3. Treatment with 30,000 units of vitamin A daily resulted in return of dark adaptation to normal within three months and complete subjective relief of the dry skin and night blindness.

This subject was typical of those who showed moderately severe night blindness, with or without mild dryness of the skin, but no evidence of hyperkeratosis or xerosis. About twenty students could be considered to fall into this category.

The average daily intake of vitamin A for each student was calculated. The values given in table 3 were utilized; they represent international units of vitamin A per ounce of food with the exception of the value for butter, which is measured in pats.⁸ To simplify calculations, average values in round number were assumed for each food. When the range given varied greatly (i.e., spinach, from 2,500 to 9,800),

⁸ Eddy, Walter H. and Dalldorf, Gilbert. The Avitaminoses. Baltimore, Williams & Wilkins Company, 1937, pp. 316-321.

a lower value was chosen. This was done so that the complete results would represent minimal rather than optimal intakes. However, since this study represents chiefly winter eating habits, the values are probably close to the actual amount of vitamin A consumed.

It was fairly easy to obtain accurate dietary histories from these students. Some cooperated by keeping food

being noticeable in most cases until after from four to ten weeks of treatment. Eleven of the fifteen subjects with dry skin regained normal skin texture, in the two cases of hyperkeratosis the condition disappeared entirely. The other four subjects with dry skin were still under treatment. Itching was relieved in each case. At the time of writing this paper, thirty-six students had regained normal adaptation, nine had improved and five were waiting to be retested.

Chart 5—International units of vitamin A consumed daily in diet by fifty persons with normal and fifty persons with subnormal dark adaptation

diaries. The results obtained are plotted graphically in chart 5. The normal group had a daily average intake of 5,560 international units of vitamin A, with a range from 3,300 to 9,000 units. The subnormal group averaged 2,445 units daily, with values ranging from 900 to 4,000 units except for one student with a value of 5,500 units. The exact distribution of these figures is well shown in chart 5. Except in one case there was no overlapping of the normal and subnormal group except in the range of from 3,001 to 4,000 units daily, which contained seventeen subnormal and ten normal subjects.

Further analysis of the dietary histories is shown in table 4. The total amount of each type of food rich in vitamin A consumed by each group was calculated. From these figures, the average for the normal and for the subnormal subject were obtained. Members of the normal group consumed from two to three times as much of each of these foods as those of the subnormal group. The exact figures are listed in table 4.

TREATMENT OF VITAMIN A DEFICIENCY

All the students with subnormal dark adaptation were treated. Capsules of carotene in oil⁹ were given to ten students, the rest receiving capsules of halibut liver oil concentrates¹⁰. A variety of doses was tried. The best results were secured when 70,000 units of vitamin A was taken orally for two weeks, followed by 25,000 units daily until the dark adaptation became normal. In other words, massive doses are given at first to replenish rapidly the depleted storage of vitamin A in the body.

The therapeutic results were striking. Subjective night blindness was relieved in every severe case the shortest time being one week and the longest five months. The photophobia usually improved at the same time. The changes in the skin were much slower, not

COMMENT

The analysis of these results allows several interesting and important conclusions to be formed. The study offers additional evidence of the reliability of subnormal dark adaptation as an indirect measure of vitamin A deficiency. More important, however, was the demonstration of the frequency of clinically detectable vitamin A deficiency. Of the entire student group of 162, approximately 35 per cent showed photometric evidence of vitamin A deficiency, while 12 per cent showed clinical evidence. Each of the students with severe subjective symptoms had seen one or more physicians. The eyes were always found to be normal, or refractive errors were corrected.

In most cases, the factors responsible for producing the deficiency had been operative for months, and in many, for years. The folly of the prolonged substitution of a sandwich, roll or doughnuts for one or more complete meals is evident. The eating habits of these students were no different from those of numerous other adults in all walks of life. It is obvious that many adults are entirely ignorant of food values or of what constitutes an adequate diet.

The worst diet likely to be chosen by an American will probably contain at least 800 or 1,000 units of vitamin A daily. This means that absolute deficiency is rarely seen. In each of the severe cases herein

TABLE 4—Consumption of Foods Rich in Vitamin A by Fifty Persons with Normal and Fifty Persons with Subnormal Dark Adaptation

	Normal		Subnormal	
	Total for Group	Average for Individual	Total for Group	Average for Individual

reported, the symptoms (night blindness, photophobia and dry skin) had persisted for years, progressing but slowly until a stationary level seemed to be reached. Xerosis was either absent or so mild as to be readily overlooked. Even in the worst cases, the night blindness was not entirely incapacitating. Usually, because of the slow development, its presence was not noticed unless the performance of some unusual act in the dark was required.

DAILY REQUIREMENT OF VITAMIN A FOR ADULTS

For many reasons the exact daily requirement of vitamin A by human beings has not been determined. Foods vary in vitamin A content with regard to season, storage, dehydration, oxidation and method of cooking.

⁹ The Carotene was supplied by the S. M. A. Corporation, Cleveland.
¹⁰ The halibut liver oil capsules were supplied by Parke Davis & Co., Detroit.

Individuals probably vary with regard to absorption, storage, conversion and destruction of vitamin A and carotene. In spite of these obstacles certain estimates are available, but they vary widely.

Harris¹¹ placed the minimal daily requirement at 1,000 units (U S P). This seems a very low figure. Stuebeling¹² set from 4,200 to 5,600 international units as the daily requirement of adults. Rose¹³ suggested an allowance of 140 international units per hundred calories for adults who have stopped growing. Growing children should be allowed twice this amount. Cameron¹⁴ advised an optimal intake of 5,000 units or over a day. Funk and Dubin¹⁵ placed the optimal requirement for adults at 8,000. Many of these values are purely estimates based on clinical impressions.

Chart 6—Progressive changes in dark adaptation curve of subject living on experimental diet containing 200 units daily of vitamin A

Using normal dark adaptation as an index of normal vitamin A metabolism allows another approach to the problem. With one exception (a subject with sinusitis) every student who consumed over 4,000 international units of vitamin A daily had normal dark adaptation. This amount probably represents close to the minimal daily requirement of healthy adults. To secure optimal benefits it would perhaps be best to allow a 50 per cent increase in this value.

Many factors, however, may influence the utilization of vitamin A. These must be kept in mind and the minimal requirement regulated accordingly.

Unfortunately, the influence of each of these factors is but poorly understood, and quantitative measurements are almost completely lacking. The Committee on Nutrition of the League of Nations suggested a daily intake of 8,700 international units of vitamin A for the pregnant and the nursing woman.¹⁶ In a study of forty-four pregnant women in the antepartum clinic of the outpatient department of the Massachusetts Memorial Hospital, it was found that only three had normal dark adaptation. Less than 10 per cent had a diet containing over 7,000 units of vitamin A daily.

That infection influences the metabolism of vitamin A has been suggested repeatedly. In the present study, the deficient group had more numerous and more serious infections than the normal group. In a special study, eight older children with active rheumatic fever were observed.¹⁷ Although they had been receiving between 5,000 and 10,000 units of vitamin A daily, each showed subnormal dark adaptation.

RELATION OF VITAMIN A DEFICIENCY TO AUTOMOBILE DRIVING AT NIGHT

Aside from its purely medical aspects, vitamin A deficiency will probably prove of great importance from the practical and legal points of view. That night blindness due to vitamin A deficiency interferes with driving an automobile was pointed out in an earlier report.¹⁸ At that time but two clearcut instances had been noted. Since then (a period of eight months) twenty-one additional persons have been seen who demonstrated this fact. Three were almost entirely unable to drive at night, six rarely did so and the remainder drove but disliked to. Cases 1 and 2 in this paper are representative. Five accidents involving such persons had been directly attributable to this symptom. In all cases proper therapy completely restored normal dark adaptation and eliminated night blindness. Several of these persons are now driving at night for the first time in years.

The complaints of these hemeralopes fell into two categories. They were easily dazzled and temporarily blinded by headlights from other automobiles. Lights which would annoy a normal person but slightly were able to deplete the low store of visual purple in the retinal rod cells. The incomplete and unduly slow regeneration of this phototropic substance left them temporarily with only cone vision or, in other words, blind for dim illumination. They experienced little difficulty while driving on artificially illuminated city streets, because cone function could be utilized. The major difficulties were experienced on dark country roads. Long drives were unduly fatiguing at night. Aside from being bothered by the dazzle of lights, these people saw the road, road edge, markers and pedestrians with great difficulty. This was particularly true after they passed an oncoming car. It is interesting to note that in no case had the correct diagnosis been made. This subject is discussed in detail elsewhere.^{18a}

EXPERIMENTAL PRODUCTION OF VITAMIN A DEFICIENCY IN HUMAN BEINGS

Practically all the work dealing with the experimental production of vitamin A deficiency has been limited to laboratory animals. It is obvious that the use of animals

is not desirable for the analysis of minor manifestations of this deficiency, in view of the subjective character of many of the manifestations

The following experiment was tried, not to gather conclusive evidence but to outline the technic of producing vitamin A deficiency in human beings for experimental purposes

A healthy man (the writer), aged 32, was used. There had been no serious sickness since childhood. A mild infection of the upper part of the respiratory tract had been present for three days in November 1936. The diet had always been adequate, and photometer tests at intervals for the preceding two years had shown normal dark adaptation in every instance. In addition, 10,000 units of carotene and 17,000 units of vitamin A had been ingested daily for three months prior to the experiment. It was felt that under such circumstances the stores of carotene and vitamin A in the body were at their peak.

The diet used to produce a pure vitamin A deficiency is shown in table 5. The vitamin A content is listed as international units per ounce of food. Such a selection of foods readily supplied an adequate number of calories and sufficient protein, carbohydrate and fat. In addition, 25 mg of cevitamic acid, 200 Sherman units of vitamin B₁ and 100 Sherman units of vitamin B in the form of brewers' yeast, and 40 grains (0.26 Gm) of calcium lactate were taken daily. Exposure outdoors on sunny days was considered sufficient to supply an adequate amount of vitamin D.

Sufficient food was eaten to satisfy hunger. The diet proved not unpalatable. It could have been enormously improved by the use on bread of a "spread" which was free from vitamin A. Fluids consisted of water and black coffee. At each meal the number of vitamin A units consumed was calculated. The intake averaged 200 units daily.

The experiment was started on March 29, 1937. Readings were obtained daily on the biophotometer and weekly by Edmund's test. The results are plotted in chart 6. On the sixth day the first photometric impairment of dark adaptation was noted. Afterward there was a steady and progressive decrease in the ability to adapt in darkness. Representative figures obtained on the tenth, seventeenth and thirty-first days are shown in chart 6.

Definite subjective night blindness was noted late in the fourth week and particularly during the fifth week. This was searched for while the subject was driving at night, entering a darkened theater and observing fluoroscopic examinations and by means of prearranged tests at home. Comparisons were made with persons with normal adaptation. This degree of night blindness would easily have been overlooked had it come on slowly and spontaneously and persisted for a long time. Accompanying the night blindness was mild photophobia, especially noticeable while the subject was driving an automobile at night.

On the thirty-first day the skin was still smooth and the eyes free from burning and there was no xerosis. At 12 o'clock noon, 80,000 units of vitamin A was taken orally, and at 12:30 a normal dinner was consumed. At 2 p.m. a photometer reading was taken and showed marked improvement. Readings were taken at twenty-four hour intervals, and 100,000 units of vitamin A was consumed daily. Within three days dark adaptation had returned to normal and the subjective night blindness and photophobia were relieved. The photometer readings obtained during the recovery phase are plotted in chart 7.

Certain conclusions can be drawn from this experiment. Moore,¹⁰ by correlating the survival period of rats on a diet free from vitamin A with the reserve of vitamin A stored in the rat's liver, and comparing the latter with the reserves stored in human livers, was able to conclude that a human being could live for six months on a diet completely free from vitamin A. However, this is the survival period. It is obvious from the experiment reported in this paper that the store of vitamin A could keep the visual purple mechanism at

peak efficiency for only one week and could not protect against subjective symptoms for more than three weeks. Incidentally, the diet used supplied 200 units daily. The worst diet encountered in clinical practice yielded 900 units of vitamin A daily. One can conclude that clinically important vitamin A deficiency is produced only after months or years of a deficient diet.

SUMMARY AND CONCLUSIONS

Vitamin A deficiency is common in adults and varies from a photometrically detectable phase to the complete clinical syndrome. In a group of medical students, 35 per cent had low photometer readings and 12 per cent had clinical manifestations of the deficiency. The chief manifestations, in the order of their frequency, were night blindness, photophobia, dry skin, dry conjunctivae, blepharitis and follicular hyperkeratosis. The factors producing the deficiency were analyzed and showed that the skipping of meals and poor choice of foods were chiefly responsible. After dietary analyses it was concluded that 4,000 international units of vitamin A daily represent the minimal requirement for a healthy adult. Infections were more numerous and severe among the deficient students. Further evidence that it is dangerous for the hemeralope to drive an automobile at night was obtained. Photometric evidence of night blindness appeared in six days and subjective evidence in five weeks after the production of a pure vitamin A deficiency in an experimental subject. Night blindness preceded gross epithelial changes.

Boston City Hospital

ABSTRACT OF DISCUSSION

DR M. A. BLANKENHORN, Cincinnati. I concur in the main with the conclusions and commend the method the speaker has just described. I have practiced somewhat the same technic in studying a few patients with marked nutritional disturbance. I have found severe night blindness, as recorded by this technic, which disappeared after treatment with vitamin concentrates. I was unable to correlate this night blindness with complaint, because the patients were not aware of blindness. I am sure that there may be difficulties of vision due to errors in diet and the patient not be aware of it. I did, however, find a number of such patients who were night blind who did not have dryness of the skin. So I am certain that one cannot correlate at present these two stigmas of vitamin A deficiency. The ophthalmologists have criticized this work because they believe not enough is known of the threshold of light perception. Ophthalmologists have made questionnaires of the complaint of night blindness and they do not find much blindness, but most of their studies made on the perception of light deal with thresholds of light so low that they fall outside the realm of testing such as Dr Jeghers has done. So I think this particular work here presented will withstand critical inspection by any one. It is true that health surveys have been made of children in large groups reporting defects of light perception which fall within the range which the ophthalmologists criticize. Dr Jeghers did a wise thing here. He threw out of his consideration most of the cases that fell in this doubtful realm. He did a very safe thing from the nutritionist's point of view, also he compared the fifty highest in the class with the fifty lowest and discarded the midgroup. A good bit of the health testing that the ophthalmologists criticize falls in this class with slight impairment of light perception. Dr Jeghers has wisely disregarded that group in this study. I should like to ask Dr Jeghers whether he finds marked and rapid fluctuation of the light threshold when testing normal persons. I have been studying a few persons whom I considered normal who fluctuated rapidly from day to day. If I were to apply rigid rules, I would say that today they are deficient and tomorrow they are all right, regardless of medication or diet. Does he find such variation? If so, how does he explain it? From seeing a few patients with severe nutritional disturbances, I get an impression that night blindness may come and

19 Moore, Thomas. VIII. Vitamin A and Carotene. VIII. The Vitamin A Reserve of the Adult Human Being in Health and Disease. *Biochem J.* 31: 155-164 (Jan.) 1937.

go rapidly and that a great deal more must be learned about the physiology of vitamin A before many clinical problems can be intelligently handled.

DR. JOHN B. YOUNG, Nashville, Tenn. Dr. Jeghers' paper is an important contribution in the field of dietary deficiencies. My associates and I can report observations similar to Dr. Jeghers. Using the same type of photometer, we detected a subnormal dark adaptation in half of fifty clinic patients, many of whose diets were suspected of being inadequate. A similar defect was found in eleven of fifty-four supposedly normal subjects whose diets were presumed to be adequate. All showed a return to normal vision when they received adequate treatment. The dietary study of Dr. Jeghers' subjects indicates clearly a deficient or borderline intake of vitamin A in the group with hemeralopia. However, such group statistics are often confusing to the physician dealing with the individual patient. He is apt to complain that while his patient shows signs of the disease the diet appears to be adequate. However, deficiencies occur as the result of one or more of three causes: (1) deficient supply, (2) imperfect absorption or utilization, (3) an increased demand. Insufficient knowledge of the latter two and failure to appreciate quantitative relationships will explain many discrepancies. With reference to the first of Dr. Jeghers' case reports referred to as a classic example of the fully developed picture of vitamin A deficiency, it must be emphasized that the description should be interpreted in the light of current ideas of this deficiency. Difficulty in driving a car at night, dryness of the skin, roughened hair follicles and slight dryness of the conjunctivae did not constitute the picture of fully developed vitamin A deficiency in even the recent past. The difference in time required by the vision, on the one hand, and the skin and other epithelial surfaces on the other, to respond to treatment is of practical importance. The former, which requires only an adequate supply of vitamin A, can be restored quickly. The latter, which involves a slow process of anatomic repair, takes much longer and treatment in cases of vitamin A deficiency should be continued long after the visual abnormality has been corrected. It should be pointed out that vitamin A is not the only substance involved in the process of regeneration of visual purple. It is brought about by a series of complex chemical reactions. Glutamine, for example, affects markedly the glycolytic activity of retinal tissue and theoretically disturbances in some of these other mechanisms may at times be involved rather than the supply of vitamin A. From a practical point of view, however, this seems very unlikely, except in rare instances, and the effect of treatment will serve in most cases to confirm the diagnosis.

DR. M. G. WOHL, Philadelphia. Full blown cases of deficiency diseases are rare in this country, especially is this true of xerophthalmia. In 1926 I had the opportunity to review this subject and was able at that time to collect from the American literature only two cases of xerophthalmia that developed on account of incorrect diet. In connection with a study of avitaminosis in diabetes, I described an instance in which a school teacher, aged 32, acquired xerophthalmia in the course of diabetes. Since then three additional cases of xerophthalmia have been reported in the American literature. In the wards of the Philadelphia General Hospital, the clientele of which is made up of the poorer classes of the community, fully developed cases of deficiency diseases, with perhaps the exception of pellagra and scurvy, are a great rarity. This at least has been my experience in the work for the past five years. Dr. Jeghers is to be congratulated on producing a pure vitamin A deficiency in an otherwise healthy adult, for dietary deficiency is more complicated in the human being than in the laboratory animal, and avitaminosis is frequently of the multiple type, as our patient who presented clinical and post-mortem signs of xerophthalmia and beriberi. It is to be remembered that in addition to the hypovitaminosis such patients suffer from general undernutrition, and the same may apply also in experimental avitaminosis. In our experience with induced avitaminosis in animals we frequently had difficulty in evaluating postmortem observations as to how much was to be attributed to pure avitaminosis and how much to undernutrition. I should like to ask Dr. Jeghers what his experience has been with the photometer for dark adaptation in patients

with hypometabolism. I have reference to the thin hypothyroid patients with dry, scaly skin, who present many features unlike those shown on the screen by Dr. Jeghers. It would be of interest to know what the basal metabolic rate was in his group of cases.

DR. HAROLD J. JEGHERS, Boston. The test is a subjective one, and for that reason the most satisfactory results are obtained when intelligent persons are studied. There may be a definite fluctuation even in the normal group. It was discovered that a slight drop in the curve of normal persons resulted if the testing was done late in the day. Really low values may be obtained if a person has remained up all night. After a night's rest the test would again be normal. No systematic study was made of cases of hyperthyroidism. Experimentally it has been shown that the thyroid gland influences vitamin A metabolism. The large number of low curves was a surprise to me. The first reaction was that we weren't doing the test right or that something else was wrong. Particularly early in the study, many of these students had two three or four tests apiece on consecutive days, usually with similar results. In addition, many were checked by the more difficult, but much more objective, method of Edmund. There was a close correlation between these two methods of testing for vitamin A deficiency. The prompt clinical response to therapy, the fact that the speed of response varied with the dosage of vitamin A and the consistent changes in the dark adaptation curves speak in favor of the specific nature of the test as a measure of vitamin A deficiency. The duration of the colds in these students was determined by the questionnaire method. I am unable to explain why it was shorter than in the group studied by Drs. Spies and Shibley.

VOLATILE SOLVENTS AS A PROBLEM IN INDUSTRIAL MEDICINE

W. J. McCONNELL, M.D.

Assistant Medical Director, Metropolitan Life Insurance Company
NEW YORK

The increasing prominence of volatile solvents in modern industrial processes emphasizes the need of early recognition of any toxic action on exposed workers which, if recognized, may lead to corrective measures being adopted. Within the past few years the number of newly perfected solvents has steadily mounted, until today well in excess of 300 are in common use, contrasted with a bare half dozen used twenty years ago. One or more of the solvents are used in ever increasing quantity and variety in nearly every manufacturing industry today either as a solvent or as a diluent. They are employed as cleaning or degreasing agents, in lacquer coatings, in dyes and cement as plasticizers, and as solvents of cellulose and gums of various kinds in a myriad of synthetic finishing materials.

The volatile solvent vapors enter the body chiefly through the respiratory passages, but appreciable quantities may either be ingested or absorbed through the intact skin. When toxic substances are inhaled, they pass into the general circulation and are distributed to the heart and to the central nervous system with a rapidity second only to that seen when they are injected directly into the veins. They can produce either a general toxic action without harm to the respiratory tract or a mixed effect, being generally toxic and locally irritant. A few irrespirable vapors act so violently in

Read before the Section on Preventive and Industrial Medicine, Public Health at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1937.
Owing to lack of space this article has been abbreviated for publication in THE JOURNAL by the omission of a table giving the classification of industrial solvents. The complete article appears in the 20th reprint.

the upper respiratory tract and lungs that their general toxic effects are secondary considerations

The absorption of vapors through the alveolar wall is accomplished by the process of diffusion, which depends on a difference in the partial pressures of the gases contained in the blood and in the inhaled air—a physiologic fact of great importance when it comes to the consideration of first aid treatment. As long as the partial pressure of the vapor in the lungs is greater than that in the blood, absorption will continue. Hence the first and most essential step in acute poisoning is the removal of the victim from the polluted atmosphere. Equally important and essential, taking precedence over any and all other measures or drugs when natural respiration has been affected, is the application of manual artificial respiration.

Substances ingested, if they do not set up sufficient irritation to cause vomiting, may be absorbed by the intestine in varying amounts, depending on their properties and their reaction with the material of the digestive tract. A large portion of the absorbed substance passes into the portal circulation and may be satisfactorily handled by the liver.

Some of the more toxic fat soluble vapors are absorbed through the intact skin. Dermatitis may be set up by the continual handling of almost any of them, either because of their fat solvent properties or because of sensitivity, natural or acquired. Many of them may also affect the eyes and any optic neuritis or paralysis in workers exposed should give rise to investigation.

It is characteristic of the quick drying lacquers that the solvent which is their vehicle evaporates with great rapidity and hence may produce a high concentration of the vapors in a confined space. The increasing use of a spray gun in applying finishes to large surfaces has greatly increased the hazard of toxic vapors in many processes. Dip and flow methods also involve the use of large quantities of solvents.

With few exceptions all volatile solvents, if inhaled in sufficient concentration for a sufficient length of time, are detrimental to health, although their early effects on the body frequently go unrecognized or are regarded as minor ailments of no consequence, because of inadequate knowledge of their physiologic properties. The concentration of vapor solvents in the air breathed depends on their volatility, which, in turn, is often dependent on their temperature and the effectiveness of ventilating equipment.

While the responsibility of finding satisfactory solutions of these new problems created by the use of solvents lies primarily in the field of industrial medicine, more knowledge of these poisons is desirable among general practitioners who see the slighter forms of poisoning. The failure to diagnose industrial poisoning is well illustrated by Lejeune,¹ a general practitioner himself, who discusses twenty-nine cases of poisoning by tetrachlorethane, benzene, benzine and trichlorethylene, which he has treated in his practice during the last few years. Thirteen of these patients had previously consulted other doctors and in twelve of the cases no diagnosis of poisoning had been made.

HYDROCARBONS

Of the various groups of solvents encountered, perhaps the most important to the physician are the chlori-

nated compounds, because of their anesthetic and poisonous action. The member of this group with which we are all familiar is chloroform. Although chloroform possesses high solvent powers, it does not find wide application in industry because of its well known anesthetic properties. Carbon tetrachloride is perhaps the most widely used solvent of this group. It is very much like chloroform but is more toxic and is used extensively as a cleaning fluid and in fire extinguishers. It has been used medically as a vermifuge in hookworm disease. Its narcotic effects are less marked than those of chloroform, but its effects on the liver, heart and kidneys are much more rapid. Carbon tetrachloride, together with other members of the group, also has a marked effect on the nervous system, probably because these are lipid solvents. There are changes in the blood in the direction of a leukocytosis, but these do not dominate the picture as they do in hydrocarbons of the benzene ring group. The effects on the heart are very important in cases of acute poisoning, because, in addition to acting as a heart depressant, there is a tendency to cause fibrillation. This means that stimulants, such as epinephrine, are a dangerous first aid measure in resuscitating persons overcome by these vapors.

Trichlorethylene is the least inflammable of the group and, because of its solvent action in fats and oils, it is used as a thinner for coatings and varnishes and as a solvent for rubber, replacing carbon tetrachloride in many instances. It is also claimed to be a less poisonous substance, but increasing evidence shows it to be far from innocuous. Reports of 284 cases of poisoning with twenty-four deaths have been collected by Stuber.² While not so damaging to the body organs, it is a profound nerve poison. It has been suggested, however, that the impurities present are responsible for its poisonous properties.

Dichlorethylene is severely toxic. Severe cases of poisoning have been reported in men who were coating the interior of beer vats, using a lacquer containing this solvent. Autopsies on men overcome by its vapors showed an excess of fat in the blood suggesting death from embolism rather than asphyxiation. Perchloroethylene causes a severe and rapid narcosis.

Tetrachlorethylene is a relatively new solvent and is less narcotic than the majority, although symptoms of drowsiness, headache, giddiness and a narrowing of the visual field have been reported from repeated daily inhalations.

Tetrachlorethane is the most poisonous of the chlorinated hydrocarbons. In acute poisoning the symptoms develop rapidly. The condition is characterized by acute yellow atrophy of the liver, jaundice, and fatty changes in other viscera especially the heart, and death frequently results. In chronic cases the blood changes are marked, leading to secondary anemia, hemoglobinuria and hemolysis. Emaciation and even jaundice may follow.

A toxic amblyopia, or an optic neuritis, has been noted by several observers in the case of exposure to chlorinated hydrocarbons. Some of this group decompose when heated and undergo chemical changes. Chloroform, dichlorethylene, ethyl dichloride, and carbon tetrachloride are oxidized to carbon oxychloride or phosgene.

¹ Lejeune E. The Frequency of Industrial Poisonings Seen in General Medical Practice. *Schweiz med Wchnschr* 66 914 917 (Sept 15) 1940 941 (Sept 26) 1936 abstr. *Bull Hyg* 12 16 (Jan) 1937

² Stuber A. *Arch f Gewerbepath u Gewerbhyg* 2 398 (July 27) 1931

Chlorinated naphthalene products used, among other ways, as a form of wax in insulating, have been clearly shown to cause severe skin troubles and have been suspected of causing fatal cases of yellow atrophy of the liver. It is interesting that these substances appear relatively harmless when cold, but when heated, despite the fact that they do not decompose or liberate chlorine and hydrochloric acid, the vapors cause acne more or less characteristic of chlorine acne.

Of the other groups of coal tar hydrocarbons, those of the aromatic series are the most important from the point of view of toxicity. The principal effect of this group of narcotics is on the hematopoietic system.

Benzene (benzol), one of the most volatile of the group, is a solvent for cellulose, gums, resins, fats and oils. Its use as a diluent in paints and lacquers and in paint removers is disappearing because of its dangerous toxic effects.

Toluene and xylene, the higher homologues of benzene, are perhaps just as toxic but are less dangerous under ordinary circumstances because they are less volatile. These, too, are gradually being replaced by the apparently less toxic hydrogenated naphthas.

High concentrations of benzene are rapidly fatal. Exposures to moderate concentrations cause symptoms similar to alcoholic intoxication at first but are followed by symptoms of progressive depression with possible parkinsonian syndrome. Repeated exposures to small concentrations of benzene cause gastro-intestinal disturbances, headaches, vertigo, gingivitis and frequently nosebleeds, and small hemorrhages of the gums and conjunctiva. Purpura may be noticed and sometimes uncontrollable hemorrhages occur, particularly if there is any surgery done. The blood undergoes important changes as a result of destruction of the blood-forming organs. Anemia and, later, leukopenia with special reference to the granular polynuclears are seen. Fatty degeneration of the blood vessels, heart, liver and kidneys frequently follows.

It may be of interest to recall that recently considerable evidence has been produced to the effect that therapeutic drugs derived from the benzene ring—such as aminopyrine—may be the cause of an agranulocytosis in susceptible individuals. Once these blood changes have taken place, they are, in the present state of our knowledge, very apt to be irreversible.

The finding of a red blood count under 4,000,000 or a white blood count under 5,000 on repeated observation, accompanied by the symptoms indicated and a history of sufficient exposure, should be considered diagnostic of chronic benzene poisoning.

Yant and Schrenk's³ method for determining increased organic sulfate in the urine is probably the best indication of benzene exposure and absorption.

Naphthalene is somewhat similar to benzene. It has a less pungent odor and probably is less toxic. Naphthalene has been suspected by a number of observers as a cause of cataract.

Among the derivatives of the hydrocarbons, carbon disulfide deserves special mention because of its varied effects on the body following repeated exposure to small concentrations. Concentrations of from 300 to 400 parts per million in the air for several hours are thought to be possibly toxic. Carbon disulfide is used chiefly in the rubber and artificial silk industry.

Chronic poisoning is characterized by persistent headache, somnolence during the day, and weakness of the limbs. Carbon disulfide is extremely damaging to the nervous system, causing polyneuritis, visual disturbances, tremors, mental confusion, severe psychosis and ataxia. An important characteristic of this poison is its effect on the higher nerve centers. Anemia is not uncommon, with occasional changes in the red blood cells and, rarely, a leukocytosis. Not only is it damaging to the eyes, but the disappearance of the corneal reflexes is said to be an early sign of poisoning. However, Wiley, Hueper, and von Oettingen⁴ quote Rodemacher as recommending the carbon disulfide level in the blood as the best indication of incipient carbon disulfide poisoning.

Petroleum hydrocarbons, which are often confused with the coal tar derivatives because of the similarity in names (benzine, naphtha) are all familiar solvents which have a mildly anesthetic action. The higher concentrations cause headache, dizziness, blurred vision and even loss of consciousness. Any chronic blood damage from this group is controversial and, if found, probably points to the advisability of looking for some other exposure or cause, particularly the admixture of one of the more dangerous types of solvents in the substance handled. Like all the other solvents, these can readily cause a dermatitis.

Turpentine vapors have a direct action on the skin, causing reddening and not infrequently an obstinate eczema. The inhalation of heavy fumes of turpentine induce symptoms of a mild narcotic poisoning. Nephritis has been reported from prolonged exposure.

PHENOL COMPOUNDS

Cyclohexanol (hexalin, adronol, anol or sexol) is a hydrogenated phenol used in pyroxylin lacquers. It is not very volatile, and it evaporates much more slowly than other solvents. It is narcotic and may cause poisoning if inhaled. From animal experiments, it is thought to paralyze the central nervous system and to be more toxic than benzene, though not as dangerous on account of its low volatility. No cases of poisoning in man are on record.

A very dangerous substance which may be used in plasticizers is orthotricresyl phosphate. This is the poison which was identified some years ago as the cause of an epidemic of "jake paralysis" from drinking boot leg jamaica ginger. These men have never completely recovered. Usually, in solvents the para and meta trisyl phosphates are used, and these do not appear to have the peculiar action of the ortho compounds, according to Hamilton.⁵

ALCOHOLS AND THEIR ETHERS

The alcohols are perhaps the most widely used of the various classes of solvents. As a group they are narcotic and injurious to the nervous system. Ethyl alcohol is used for research and analytic work in educational and industrial laboratories and is employed for many scientific and medical needs. It is a solvent for gums, resins and many organic and inorganic compounds. Methanol is used largely in the manufacture of pyroxylin plastics, varnishes, textile soaps and wood

stains, as well as in extraction processes. One of its most important uses is in the manufacture of formaldehyde. Isopropyl alcohol is used as a substitute for ethyl alcohol, mainly in perfumes and high grade toilet preparations. It is claimed to be an effective germicide and is used in lotions, liniments, liquid soaps and antiseptic solutions. Normal butyl alcohol is the most popular and widely used of the higher alcohol group. Large quantities enter into the manufacture of nitrocellulose lacquer.

Generally speaking, the toxicity of the alcohols increases with the molecular weight, but the decreased solubility and volatility of the higher alcohols partially offset the danger of exposure to concentrated vapors. The exception to this rule is methyl alcohol, which may be produced synthetically or by distillation of wood. It is a powerful nerve poison which specifically affects the optic nerves and may result in blindness and death. Owing to its slow oxidizing action in the body, its effects are cumulative, and severe poisoning may result from continued exposure to even small concentrations, without any early warning symptoms. Experimentally, it has been shown to cause poisoning through skin absorption.

Although amyl alcohol and fusel oil are more toxic when taken by mouth than any other way, they play a minor role in industrial poisonings. Butyl alcohol produces liver and kidney damage in animals exposed to its vapors.

Tertiary alcohols are more toxic than secondary alcohols, and primary alcohols are the least toxic. Isoalcohols are usually less narcotic than the corresponding normal alcohols. A most interesting case of toxic encephalopathy has been reported, however, in a woman who used a mixture of solvents containing 3 per cent dimethyl phthalate, 3 per cent cellosolve and 74 per cent isopropyl alcohol in "fusing" collars with a hot iron.⁶

A larger group of newer solvents which is rapidly coming into greater prominence is the alcohol-ethers, or oxides, and the furfurals. Often these may be compounded with phthalic acid, oxalic acid or formic acid, thereby introducing the possibility of a second toxic agent. Our knowledge of this group is largely based on animal experimentation, though a number of cases of industrial poisoning have been reported. As a group, they are narcotic or anesthetic, and some of them are known to be toxic in the higher concentrations, but there is little information concerning their chronic effects or the maximum permissible concentration.

Diethylene dioxide (dioxan), also used as a lacquer solvent, is irritating and unpleasant, and these effects were thought to constitute a sufficient warning that concentrations were approaching the danger point. In England, however, five deaths were recorded as being due to the fumes of dioxan, with severe inflammation of the liver and kidneys.

ESTERS, KETONES, GLYCOLS AND THEIR ETHERS, AND FURFURALS

Esters, ketones, glycols and their ethers, and furfurals constitute probably the most important group of solvents for nitrocellulose and cellulose acetate. All are narcotic in sufficiently heavy concentrations and in proportion to their volatilities. Although fatal accidents are very rare, evidence is beginning to appear pointing to their physiologic effects as being more dangerous

than they were formerly considered. Reference to a reported death in one man from the inhalation of amyl acetate and another from the inhalation of ethyl acetate is made by A. V. St. George.⁷ In the former, edema of the glottis and diffuse irritation of the respiratory and gastro-intestinal tract were the chief pathologic changes, and in the latter there was a marked congestion of the viscera and the eyes, almost entirely liquid blood in the vessels, petechia-like hemorrhages throughout the serous cavities and mucous membranes, and a pungent odor on opening the body.

Amyl acetate is readily recognized by its sweet, sickening odor, and it is generally known as "banana oil." Its vapors cause irritation of the throat, burning of the eyes, vertigo, drowsiness and gastric irritation. In experimental animals the inhalation of amyl acetate produces chronic inflammatory changes in the respiratory system, parenchymatous degeneration of the kidneys, and fatty livers. The blood shows a moderate leukocytosis with a secondary anemia.

Methyl, ethyl, propyl and butyl acetate are other members of the ester group of solvents. Methyl acetate is sometimes used as a substitute for acetone, but it is not widely used, because of its acid reaction with water. Ethyl and butyl acetates are the most widely used of all the solvents of nitrocellulose.

Of the ketone group of solvents, acetone is probably the most widely used, and it is one of the most powerful solvents known. The impurities present depend on the method of manufacture and are no doubt responsible for some of the toxic symptoms that are encountered. Its narcotic action in animals is more pronounced than that of chloroform. The examination of the blood after continued inhalation shows a destruction of the red cells and hemoglobin. It does not appear to produce chronic tissue damage as long as the vapor concentrations are low, even though exposure is prolonged.

Several ketones of higher molecular weight have been recommended as good solvents for nitrocellulose, but they have little or no effect on cellulose acetate. The more important members of this group are methyl-propyl ketone, or pentanone, and methyl-butyl ketone, or hexanone. Their acute effects on guinea-pigs were studied by Yant and his colleagues,⁸ who report that death results from a state of narcosis rather than from the irritation of the lungs. All fatalities occurred during the exposure. Men momentarily exposed to approximately 13 and 5 per cent of pentanone vapor and to 1.23 and 2 per cent hexanone vapor complained of irritation of the eyes and nasal passages and of a characteristic strong odor.

Of the glycols and their ethers, the mono-ethyl ether of ethylene glycol, or "cellosolve," is the most important solvent of this class. It is a stable liquid and it is used as a solvent for nitrocellulose and resins, and it offers the advantage over most other solvents of similar boiling point in being nearly odorless. The acute physiologic response of guinea-pigs to air containing its vapor was determined by Waite, Patty and Yant,⁹ who found

the cause of death, in the animals who died twenty-four hours after exposure, to be congestion and edema of the lungs, and in animals dying three days after exposure, to be bronchopneumonia. Two of the investigators who breathed 0.6 per cent cellosolve vapors for a few seconds reported the atmosphere to be irritating to the eyes and to have a very disagreeable odor. They thought that the odor and the irritation were sufficiently disagreeable to make one desire to avoid a like exposure.

Furfurals are excellent solvents and are used considerably in industry. The vapors are irritating and are very damaging to the eyesight of some persons.

SUMMARY

An estimation of the extent of any health hazard resulting from solvents and mixtures of solvents can be reached only after careful analysis of individual circumstances.

The mere knowledge that volatile solvents are used in certain industrial processes does not justify the conclusion that all illnesses among the working personnel may be attributed to exposure to these substances. Solvent vapors can be, and frequently are, confined within a closed system or are prevented, by proper exhaust equipment, from escaping into the plant atmosphere. In doubtful instances the diagnosis of industrial intoxications through inhalation should be further confirmed by chemical analyses of the air breathed. Such analyses are also essential in determining the efficiency of measures instituted to prevent the diffusion of these vapors into the breathing zone of the workers.

The difficulties encountered in determining the concentration of vapors in the plant atmosphere are many. In the first place, distinction must be made between vapor concentrations associated with plant operations and those resulting from accidents and irregularities in operation. Under normal operations they may be present in the air in very low concentrations, which may require special technics in collecting air samples and selective methods of analysis. When two or more solvents are present in the air in combinations at the same time, it is frequently impossible, by existing methods of chemical analysis, to identify and estimate individual components, although they can be differentiated and estimated as groups. Benzene and its homologues may be detected by a rather intricate colorimetric method, while carbon disulfide must be estimated by microtitration after absorption in an alcoholic potash solution. The chlorinated hydrocarbons may be determined by a combustion method in which the liberated hydrogen chloride is absorbed. Other groups, such as the alcohols, esters, ethers and ketones, may be determined or estimated by various analytic methods. When two or more members of a group are present, it is usually impossible to separate them and the results of the analysis must be recorded on the basis of the more toxic material. When a mixture, such as a lacquer thinner which may contain methyl and ethyl alcohol, acetone, benzene, ethyl and amyl acetate and butyl cellosolve, is under consideration, the problem becomes involved. It then becomes necessary to use a method that will determine the total amount of solvent vapor present. This may be done quantitatively by freezing out the vapors with liquid air, by absorption with activated charcoal or silica gel, by a carefully calibrated interferometer, or by a combustible gas indicator that will indicate the presence of all inflammable solvents present. Many of these methods of analyses, however, are far from sat-

isfactory and considerable research work must be conducted before the analyst and the industrial hygienist will feel confident of the results.

The recognition of industrial poisoning from the inhalation of volatile solvents is generally quite difficult. Acute and fatal poisonings do occur, but usually under circumstances that disclose the responsible agent.

The detection of volatile solvents in the body after death from an acute poisoning is possible for all substances having a boiling point below that of water by the micro methods of Gettler¹⁰ and others. This method depends on condensation of the material in tubes immersed in freezing mixtures. In the living or in those who have lived a few days before death from poisoning, these small amounts cannot be detected. Examination of the urine is revealing in some cases, and examination of the blood tells the story of cumulative exposures in others. Nothing much is known regarding the detection of halogenated hydrocarbons, but with brominated compounds there will be some bromine in the urine, and it is possible with chlorinated hydrocarbons that organic chlorides may prove to be indicative of absorption.

Industrial poisoning, however, is characteristically chronic in form. The worker's health is gradually impaired by repeated small inhalations of the solvent material, and evidence of toxemia may not arise for several years. Although solvents do not accumulate in the body, as does lead for example, there does occur an accumulation of effects from repeated daily inhalations. Seldom do these exert their influence on a single organ. Changes usually are found in the blood, kidneys, liver, heart, nervous system and other organs.

The clinical picture and symptomatology may be similar for many solvents and a diagnosis frequently must depend on a correlation with the chemical analysis of the air breathed and evidence revealed by the examination of the blood and the urine.

The prevention of poisoning by inhalation is dependent entirely on the measures employed against the diffusion of vapors into the plant atmosphere. There is no single measure of control that is applicable to all operations. A combination of measures usually must be employed to insure success. These include the substitution of harmless or less harmful solvents for harmful ones, the segregation of vapor-producing operations, enclosure of processes which confines the vapor, mechanical methods including local exhausts applied either above or below the processes according as the vapors to be entrapped and removed are lighter or heavier than air and increased general ventilation to insure rapid changes of air, personal protective device, instruction of workers regarding the hazard, and competent medical supervision.

Personal protective devices frequently offer inadequate protection. Respirators should be used only in an emergency or when the exposure is intermittent and should be of such a type that the worker breathes air from an uncontaminated source. Skin absorption can best be prevented by cleanliness of body and clothing. The absorption of vapors through the intact skin, especially if spilled or absorbed in the clothing, must be borne in mind. This is particularly true of the fat soluble solvents.

ABSTRACT OF DISCUSSION

DR HENRY FIELD SMYTH, Philadelphia As chairman of the Industrial Hygiene Section of the American Public Health Association, I have abstracted more than 400 papers on volatile solvents during the past three years. Out of 322 papers, 122 discussed benzene 108 chlorinated hydrocarbons, thirty-seven petroleum products, twenty-nine alcohol esters or ethers, and twenty-six carbon disulfide. 1,714 cases of injury from carbon disulfide were reported, 375 from chlorinated hydrocarbons, 323 from benzene and derivatives 186 from petroleum products, twenty-seven from formaldehyde and eight from alcohol. Forty-three fatalities mentioned in these papers have been attributed to chlorinated hydrocarbons, twenty-five to formaldehyde, sixteen to petroleum products, twelve to benzene or derivatives, six to carbon disulfide, and one each to alcohol and turpentine. And, by the way, there is no volatile solvent much mentioned in the literature which some one at some time has not drunk in search of a "kick." As chlorinated hydrocarbons have created a great deal of interest recently, I have considered those separately, with 108 papers reviewed, fifty-seven of them devoted to carbon tetrachloride, twenty-one to trichlorethylene seven to chloroform, four to chlorobenzene and nineteen scattered or referring to mixed solvents. Of the cases of injury from chlorinated hydrocarbons reported, trichlorethylene leads the list with 299, carbon tetrachloride follows with sixty-five, methyl chloride five, tetrachlorethane three, ethylene dichloride and chlorobenzene one each, and mixed solvents one. I am opposed to the practice of selling any of these chlorinated hydrocarbons for dry cleaning in gallon packages to the consumer, no matter how they are labeled, for the labels are not read or understood. One reads time and again of a housewife who buys a gallon and washes half a dozen dresses in a small room, hanging them up to dry while she goes on working. She does everything possible to assure that she be poisoned and she too often is. If the materials were sold to the consumer in pint containers, these regrettable accidents would happen less frequently and much prejudice against these really useful materials would be avoided.

DR LEON LEWIS, Newark, N. J. I should like to ask Dr McConnell about the toxicity of common household insect sprays and about the actual toxicity of glycols, particularly ethylene glycol and diethylene glycol.

DR WILLIAM THAU, Boston I should like to ask Dr McConnell how certain poisoning with many of the drugs he cited can be prevented. It is known that in the hospitals, the operating rooms and particularly in the laboratories, volatile solvents such as ether, chloroform, solution of formaldehyde, xylene and many dyes are almost constantly handled by the technical staff. Sometimes tragic results, for instance an optic atrophy, can be cured, if it is not too late. But how can one prevent such ill effects while one is always exposed to the action of these solvents?

DR HAROLD B. WOOD, Harrisburg, Pa. There is a large amount of spraying done where fruit trees grow, and I should like to ask Dr McConnell whether he has taken that into consideration.

DR MILLARD KNOWLTON, Hartford, Conn. I should like to ask how many of these volatile solvents are known to be carcinogenic in character. Does the increase in the use of volatile solvents account for the increase in lung cancer?

DR ZOLTON T. WIRTSCHAFER, Cleveland I should like to ask the author whether he agrees with Dr Smyth in the statement that he does not believe that oxidation of carbon tetrachloride goes on in the body. I believe that it goes on in the lung following exposure. I believe that carbon tetrachloride gives off phosgene in small amounts in the lung. Graham, in his experimental work about twenty years ago, demonstrated the presence of hydrochloric acid in the lungs and liver of animals after exposure to carbon tetrachloride. The acid was a further oxidation product of carbon tetrachloride. The reaction undoubtedly is $\text{CCl}_4 + \text{H}_2\text{O} \rightleftharpoons \text{COCl}_2 + 2\text{HCl}$. Hence phosgene is an important factor in the pathogenesis of carbon tetrachloride intoxication.

DR R. R. SAYERS, Washington, D. C. One thing that has been done that might be emphasized is the labeling as carried out by cooperation with the manufacturers in advance of the

law. That does not prevent the hazards, as Dr Smyth has called to our attention, but it does give the physician and others competent an opportunity to advise the users of the hazards to which they are exposed. At the present time all halogenated hydrocarbons are being properly labeled when they contain 15 per cent or more of a volatile halogenated hydrocarbon and whether it is chlorinated bromide, iodine or fluorine. Fire extinguishers are being labeled showing that they contain carbon tetrachloride in excess of 15 per cent—that is when they do. This does not apply to the very small packages, but it does apply to all packages of 15 ounces or more, as a matter of fact, even those small packages of carbon tetrachloride in the ten cent stores are so labeled. Many of the other toxic volatile solvents are also labeled as to the toxic substances they contain. I should like to emphasize another fact that Dr McConnell called to our attention, that most of these volatile organic hydrocarbons are toxic if breathed in sufficient concentration but that they may be used with proper precautions. The outstanding precaution is to keep the man from breathing it by a closed process, having good exhaust equipment, good general ventilation and personal protection.

DR C. P. MCCORD, Detroit Dr McConnell referred to organic silicon compounds. I believe he made some mention of organic silicates. We in Detroit are in the midst of a study of that group of solvents. At the present time we have just completed a study on ethyl silicate. We anticipated that there might be some toxicity from ethyl silicate analogous to silica. Much to our surprise, we found an enormous toxicity from ethyl silicate which apparently is unrelated to the toxicity now associated with silica. We have introduced the ethyl silicate into small animals intraperitoneally, intravenously and orally and have applied it to the skin. When so small a quantity of ethyl silicate as 0.02 cc per hundred grams of animal weight is introduced intravenously, the animal dies within five minutes. The point of action is limited to the capillaries of the lung tissue, with slight involvement of the capillaries of the heart. Within five minutes there is hemorrhage into the lung sacs with some rupture of the lung sacs, and rupture of the capillaries of the lung, and apparently death is due, in the case of rabbits to air aspirated through the ruptured air sacs leading to air emboli. It appears that connected with silicon compounds there are other toxicities apart from the action of silica, and in the group of organic solvents in the organic silicon group there appears to be a new and interesting field, of which ethyl silicate appears to be an outstanding item.

DR W. J. McCONNELL, New York Some very interesting problems have been brought up in the discussion. I am particularly interested in the evidence which has been produced recently from the possibility of oxidation of carbon tetrachloride in the lungs, that is, the reduction of the carbon tetrachloride in the oxyhydrochloric acid and phosgene. The evidence produced certainly appears to be logical and the evidence as presented in some of the recent literature seems very convincing. Naturally, there is great possibility of the formation of phosgene particularly when carbon tetrachloride is sprayed on hot metal and when fire extinguishers are used in confined spaces. The cancer-producing properties of chlorinated compounds present an interesting subject and the doctor who asked that question will be interested in an exhibit in the preventive hygiene section which demonstrates some skin cancers in mice. I suggest that those interested see the exhibit and the action on the skin of some of these compounds. Regarding insecticides and fruit sprays I believe that all of these may be said to be toxic. Of course in these sprays the chief toxic substances are the nicotine and lead arsenate compounds. Of the glycols, ethylene glycol or 'cellosolve' is the most widely used. It is a stable liquid and an excellent solvent for nitrocellulose and resins. The Bureau of Mines has made a study of this solvent using animals for the exposure although two of the investigators also exposed themselves to low concentrations. The cause of death in the animals was due to congestion and edema of the lungs. The men themselves found it to be rather irritating and complained of a disagreeable odor. Regarding the preventive measures, particularly in hospitals where the smaller quantities of various solvents are used I feel that the danger of toxic exposure under those conditions usually results from spilling the substance. The quantities used in hospitals and in labora-

tory work are fairly small, but there is a possibility, where solvents in quart bottles or gallon jugs are standing around on laboratory desks, of their being knocked over and broken. I think that the chief caution is to use them in smaller quantities and in metal containers equipped with stoppers that will not come off if the containers are knocked over, so that the material will not spill. The real preventive measure is to prevent the dissemination of the fumes, either by local exhaust systems and good general ventilation, or by using these substances in closed systems. The latter methods are more applicable to industrial processes than to preventive measures for small quantities used in hospitals.

EVALUATION BY CONTROLLED SERIES OF VAGINAL TRICHOMONIASIS THERAPIES

H. CLOSE HESSELTINE, M.D.

CHICAGO

Vaginal trichomoniasis is one of the very common gynecologic clinical entities, and yet, in spite of numerous American and European publications in the last one and one-half decades, controversies continue unabated, especially on the subject of therapy. There are considerable differences also in the criteria employed to diagnose cures. Today the drastic scrubbing procedures have been almost replaced by a dry technic, with the patient self-administering much of the treatment. The type of vehicle, nature of the medicaments and method of treatment are too divergent and unrelated to review at this time. Because too few controls have been established, the favorable reports of many preparations have yet to be properly confirmed. Notable exceptions are the reports of Bland and Rakoff¹ and Pattysen.² Consequently, it was deemed wise to observe the therapeutic effect of three arsenical, one silver picrate and two lactose preparations and their respective controls on obstetric and gynecologic patients. The importance of prophylactic, as well as curative, therapy is emphasized. Only the lack of clinical material has restricted the scope of this study.

A small number of the regular clinic personnel treated the patients in accordance with a prescribed routine and with the assignment of control cases. So far as was feasible, the regular (or special) preparations and the control materials were coded. Such safeguards may eliminate, perhaps, some of the otherwise unavoidable experimental errors of observation and thus aid materially in pointing out the merits of procedures and preparations.

PROCEDURE

The therapeutic agents were studied primarily for their curative effect. Cervical erosion, urethritis and other associated inflammatory lesions were treated by appropriate means only when such lesions were obvious. Examinations of the urinary and intestinal tracts were not made as a matter of routine, nor were the husbands of all the patients available for examination. However, a special study for foci of infection was undertaken when patients did not respond to the therapeutic agent in question. Special periods at the clinic were allotted,

and the patients were treated as often as possible by the same physician. This centralization favored proper supervision of patients, clinic physicians and technic of treatment. The results obtained under these conditions should indicate significantly the value of the preparations and procedures in question.

The five supposedly active medicaments were acetarsone (Merck), acetarsone (Winthrop), carbarsone (Lilly), silver picrate (Wyeth) and lactose with citric acid or kaolin. The control patients received the preparation minus the supposed active medicament, i. e., the vehicles alone were used. The patients were assigned in rotation, every other patient being used as a control, except in the lactose series. Unless a time interval was set by the proponent of a preparation, the Chicago Lying-in standard (Adair-Hesseltine³) was used for determining cures. To be diagnosed as cured by this standard the gynecologic patient must go through two consecutive menstrual periods without treatment, remain free from symptoms and present no clinical or laboratory evidence of the disease. The pregnant patient must fulfil these requirements over a period of two months during pregnancy or before and after parturition.

* Acetarsone (stovarsol).

† Materials furnished by Merck & Co.

In the accompanying tables the ages were omitted because they fell well within the limit of experimental range. All the patients were adult women. The youngest was 18 and the oldest 55.

Gellhorn⁴ reported the use of 12.5 per cent acetylaminohydroxyphenylarsonic acid (acetarsone) in equal parts of kaolin and sodium bicarbonate. His standard dose is 1 teaspoonful, which contains 7½ grains (0.5 Gm.) of the drug. The treatment is administered by a special blower two or three times a week. Douches are not permitted. He stated that six treatments should cure obstinate cases. This procedure was followed exactly throughout. The control material contained the same ratio of kaolin and sodium bicarbonate, but the acetarsone was omitted. The results were judged on a basis of four weeks' treatment, as suggested by Gellhorn.

About four years ago acetarsone in special carbohydrate material (partially hydrolyzed and partially oxidized) began gaining favor in Germany. The material for this study was dispensed entirely in tablet form. From two to four tablets were ordinarily placed about the cervix by the physician, and the patient was instructed to insert two each evening into the vagina. Office visits were once a week for the first two or three

times and later at longer intervals. Douches were not allowed. The number of tablets was decreased as the condition improved. The special carbohydrate material minus the acetarsone was used for the control.

Drabkin's⁵ carbarsone (*p*-carbamido-phenylarsonic acid) routine has been used only a comparatively short time. Briefly, for the first week the patient at bedtime takes a soapsuds enema, followed by a plain water enema, and then inserts into the rectum a carbarsone suppository. Immediately a soapsuds douche followed by one of plain water is taken, after which 5 grains (0.3 Gm.) of carbarsone and 5 grains of sodium bicarbonate (dissolved in 2 teaspoonfuls of water) are injected into the vagina and retained. The next morning one carbarsone suppository is inserted into the rectum and one into the vagina. This routine is repeated each night and morning for the first week. Thereafter it is decreased gradually by weekly steps. Lactic acid or vinegar douches are used as necessary and daily during menstruation. The rectal therapy is discontinued after three weeks. If the condition is not cured in one month, or if it recurs later, the routine is repeated. The control material was the same throughout but lacked the arsenical compound.

The silver picrate compound of Buxton and Shelanski⁶ required weekly visits for the insufflation of kaolin and the silver salt. The patient inserted each evening on retiring a medicated boroglyceride-gelatin suppository. The control material was free from silver picrate.

Adair and Hessestine³ reported that 95 per cent lactose and 5 per cent citric acid tablets and powder gave a high degree of success in cases of vaginal trichomoniasis. Each tablet contained about 2 Gm. of the mixture. After their value became evident, control cases were started, plain lactose tablets or equal parts of lactose and kaolin being used. From this time on each case was assigned in turn to one of the three preparations. The plain lactose perhaps serves best as the control.

RESULTS

Let it be remembered that the interpretations or comparisons of regular and control materials are only for each unit. Comparisons with other materials would be unfair because the experimental conditions were not identical or simultaneous. The study was to evaluate the influence of so-called specific materials and the influence of the vehicles on the course of the disease and not primarily to compare one so-called specific material with another. The regular, as well as the control, materials were furnished for the most part by the respective companies. These companies, unsolicited, requested the clinical trial and willingly consented to the establishment of controls.

The results of acetylaminohydroxyphenylarsonic acid (acetarsone) in 12.5 per cent concentration in sodium bicarbonate and kaolin, as recommended by Gellhorn,⁴ and its control were observed in only thirty-four patients long enough to analyze. Other patients started on the treatment did not complete the course and naturally cannot be included. Table 1 shows that four of the seventeen controls and four of the regular series were unimproved. The average periods of treatment were identical, and only gynecologic patients were used. No

untoward results or complications resulted from the use of the arsenical mixture. Certainly no particular merit was evidenced.

In table 2 the results of acetylaminohydroxyphenylarsonic acid (acetarsone) in the ten obstetric patients are shown to be excellent, but the number of patients is entirely too small. The two gynecologic groups had the same number of failures. Although there may be definite merit in the regular preparation, it is not enough

better for its superiority to be established positively here. Again, eighteen and twenty-one patients, respectively, are too small a series from which to draw positive conclusions unless there is a great difference in the results. Thus, acetarsone prepared by another company did not show a pronounced specificity.

Nine cases, as summarized in table 3 (*p*-carbamido-phenylarsonic acid [carbarsone] and its control), are too few for final conclusion. These are included only because the experiment is still in progress. The procedure as outlined by Drabkin⁵ is rather detailed and time consuming, and some objection and lack of cooperation on the part of the patients were encountered. Rectal therapy is surely a prophylactic measure. It is an interesting observation that the control material has given cures in all four control patients.

Table 4 shows that three of the twenty-two patients treated with the regular silver picrate material were unimproved while only two of the nineteen controls failed to be benefited. This apparent discrepancy in the results of the silver picrate is unimportant, since it falls well within the experimental range. Furthermore, no untoward results developed, and some of the patients did get very satisfactory results from the substance. A sufficiently large series might not only give a reversal of these results but even show an advantage for the regular silver picrate preparation.

The data of Adair and Hesseltine³ (table 5) show that lactose alone gave about a 2 per cent better result than did the citric acid or kaolin mixtures. There is no indication that citric acid or kaolin prolonged appreciably the period of treatment. Citric acid in 5 per cent concentration may be irritating, and apparently it did not contribute therapeutically. On the other hand, the

kaolin mixture was associated with less watery vaginal discharge. Again the control comparisons were within the experimental range.

Table 6 shows that by pooling the data on the arsenical preparations and their respective controls little difference is revealed between them. This likewise applies to the lactose group.

COMMENT

Thus, it becomes evident that good results may be obtained with various agents in approximately 85 to 90 per cent of the patients, while the remaining 10 to 15 per cent may not remain relieved or may even fail to be improved. Even though many husbands whose wives were in the unimproved groups refused urologic examinations, three of those examined were found to have prostatic infections. Such observations have already been reported by Drummond,⁸ Cornell and Riba,⁹ Karnaky,¹⁰ Adair and Hesseltine³ and others. Allen, Jensen

and Wood¹¹ have demonstrated the likelihood of foci in the urethra and bladder of some patients. Karnaky¹⁰ and others have demonstrated trichomonads in the

intestinal tract, but some controversy still exists as to whether any of these are the vaginal type. Therefore it seems that to improve the results of therapy for vaginal trichomoniasis one must not only cure the disease but eliminate the source of reinfection. Reinfection may occur so frequently and rapidly that therapy is of little aid. Hence failures may represent in part persons not having proper prophylactic care or instruction against reinfection.

The fact that vaginal mycosis did develop during or immediately after completion of therapy with silver picrate and with acetarsone indicates that the vagina was not at that time an unfavorable nidus for the fungi. This clinical observation parallels the histologic evidences that the normal vaginal epithelium in pregnancy is rich in glycogen-like material.

The biologic state of the vagina appears to be highly important. The works of Cruickshank and Sharman,¹² Plass and Oberst,¹³ Adair and Hesseltine,³ Bland and Rakoff¹⁴ and others reveal that the vaginal acidity, the glycogen-like content of the epithelium and the bacterial and cellular flora are intimately related. The normal relationship is disturbed in vaginal trichomoniasis by a

lessening of the vaginal acidity, a decrease in the glycogen-like material and a conversion of the vaginal flora to type 2 or 3.

A plea is made for the establishment of adequate and proper controls when one makes such a study and especially before recommending new preparations to members of the profession. Certainly any ethical pharmaceutical house would endorse this attitude and would cooperate if an honest evaluation was desired. In establishing controls it is urged that one adhere strictly to a routine and assign alternate cases to the control series and employ codes for the regular and control preparations whenever possible to eliminate further unavoidable personal prejudice in observations and interpretation of the therapeutic results. Moreover, before one can state correctly that any preparation is superior to others one must have a series sufficiently large to exclude at least some of the experimental errors.

CONCLUSIONS

1. The majority of patients with vaginal trichomoniasis can be benefited by more than one therapeutic material and method.

2 Probably in from 8 to 15 per cent of the cases of vaginal trichomoniasis particular care should be taken to eliminate foci of infection from the patient's rectum or urethra and bladder, or from the husband's urethra and prostate, and perhaps from other sources still undetermined

3 The physiologic restoration of the vagina is apparently of paramount importance in accomplishing cures

4 An adequate and proper control should be employed in the evaluation of the merits of any procedure or preparation

5848 Drexel Avenue

ABSTRACT OF DISCUSSION

DR A E RAKOFF, Philadelphia Interesting as are the uniformly high percentage of cures obtained by the various methods, my attention was attracted by the almost equally good results in the control series, treated with relatively inert substances such as kaolin. This is not in accord with my experience since only 10 per cent of a group treated by kaolin insufflations alone responded permanently, although almost all were temporarily relieved. It is notable that the drugs employed were all in a dry form. It is the present consensus that "dry antiseptics" affords the most successful basis for elimination of the flagellates. Two preparations were insoluble pentavalent arsenicals, acetarsone and carbarsone. Dr Bland and I made a study of these drugs plus a related soluble derivative, sodium-methylene-sulfon amino-hydroxy-phenyl-arsenate. The latter was more effective clinically and in vitro. Dr Hessel-tine pointed out that a plan of treatment based on the associated pathologic conditions is frequently more important than the choice of an antiseptic. Thus the realization that organisms are harbored in surrounding structures may mean the difference between cure and recurrence. In my experience the urethra and para-urethral structures are the most common offenders, since trichomonads are frequently found here. I am persuaded that a few organisms harbored in the cervix may also be the source of recurrences. The male is probably a source of reinfestation in a small group of cases. I found the organisms in about 6 per cent of a group of men. The anterior urethra was much more commonly the seat of infestation than was the prostate gland. The intestinal tract is rarely if ever the source of vaginal infestation. Evidence indicates that the vaginal and intestinal trichomonads are morphologically and culturally distinct and that in this climate intestinal infestation is relatively uncommon. Experimental inoculations with the intestinal forms were unsuccessful, whereas I have produced the infestation with vaginal trichomonads. Administration of toxic drugs by mouth or bowel to eliminate an intestinal infestation whose existence is not first proved is hardly justifiable yet many patients are treated in this fashion. Examination of the vaginal bacteria affords a reliable indication of progress during the course of treatment. Doderlein's bacilli tend to become reestablished with the disappearance of the trichomonads. Lactose or lactic acid douches are sometimes helpful in favoring this return after preliminary chemotherapy.

DR H CLOSE HESSELTINE, Chicago I have not been able to confirm Dr Rakoff's observations of finding trichomonads in the cervix, although others agree with this statement. Might not these flagellates be due to contamination by the vaginal discharge? Dr Curtis has just reminded me that one should be very cautious as to what one considers cures. I agree heartily with his views. Cures can be established in part by repeated examination over a sufficient time. I used the words "uncured" and "cured" to simplify tables perhaps that is incorrect. I have reviewed the cases becoming positive after intervals of two months following menstruation and I believe it is very probable that some of these may represent reinfection rather than recurrence or exacerbation. May not these reinfections be comparable to colds? A patient may have a cold one month and again in a few weeks. Would this be a new cold or does it mean that the patient is more susceptible to colds? I feel that the same rules apply here. Until more is known about the sources of spread some of our problems will remain unsettled. The problem of therapy is yet unsettled also.

INTENSIVE CASE FINDING WORK IN TUBERCULOSIS

HENRY F VAUGHAN, DR PH
AND

BRUCE H DOUGLAS, MD

DETROIT

There has been a definite reduction in the death rate from tuberculosis in the United States, the rate now being less than one-third that which obtained at the turn of the century. However, the combat with this age-old foe of mankind has by no means been completed. Although displaced by heart disease, cancer and pneumonia at the summit of the causes of death (for all ages), in the very prime of life (from 20 to 35 years) tuberculosis still ranks first as a cause of death. There are not less than 500,000 sufferers from this disease in the United States at the present moment. Let us not be lulled into any false sense of security from past accomplishment, let us attack this disease with the same vigorous attitude with which we confront small-pox or diphtheria. Health departments have been prone to accept the crumbs from monies spent for social betterment. We have been too reticent in a fight in which modern tools are at our disposal. Possessing knowledge, we are derelict in our duty when we fail to use every artifice and ingenuity in winning and maintaining public confidence and support, which alone can provide the wherewithal to deal intelligently with a pestilential disease.

How can so many health officers remain complacent knowing full well that more than 80 per cent of all tuberculosis cases reported to health departments are already in an advanced stage? How successfully could we maintain our warfare against diphtheria and small-pox if four out of five cases were officially reported to the health department only shortly before death? Why not apply the same reasonable procedures in epidemiology to tuberculosis as we daily employ in our attack on other communicable diseases?

We can all agree that the local health officer should play a commanding part in the fight against tuberculosis even though he may not have every detail as a function of his department. It is his responsibility to see that a program of prevention is carefully planned and executed. The school health service, the hospital care of patients, the health education program, and many other essentials may be carried on by voluntary agencies or other public agencies not a part of the health department. In every instance, however, the health officer must assume responsibility for the community program. He must be a planner, a coordinator, and take full authority and responsibility to see that the various units, organizations and individuals function smoothly in their respective fields. The ideal condition demands the establishment on a full time basis of an efficient local health service, the employment of a well trained public health administrator assisted by the essential technical personnel and blessed with reasonable financial support. A tuberculosis program cannot be successful without the cooperation of all agencies concerned with health education and the active participation of the medical profession, individually and collectively.

No intelligent progress can be made in combating an enemy unless we know his whereabouts and in the case

From the Detroit Department of Health.
Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1937.

of tuberculosis we know the location of but a small percentage of the sources of infection—the true spreaders of disease. Are case finding facilities adequate when less than one out of every five reported cases are minimal? For each annual death from tuberculosis there should be from five to ten known living patients. To find these hidden sources of infection requires active and continuous application of case finding service in those geographic areas and in those fractions of the population in which tuberculosis is known to be most prevalent.

Health departments have done reasonably well in providing clinic facilities, dispensaries, medical and nursing service and, in most communities, an examination of school children in the danger age. Some progress has been made in providing hospital and sanatorium care. As a whole, adequate facilities do not exist for the isolation of the infectious case and for the prompt and efficient treatment of the early case. Some communities, however, have increased hospital facilities until they have two or more available beds for each annual death from tuberculosis. In an industrial city this seems to be the minimum standard compatible with adequate treatment.

Briefly stated, the task in tuberculosis control is, first, to find the minimal case and, second, to isolate the infectious case, preferably in a hospital or sanatorium, unless this can be done under suitable home conditions. In any event the open case must be taken out of circulation and cared for under conditions that will permit the employment of collapse therapy. The failure of any program that does not begin to operate until the patient is aware of symptoms has been stressed many times and was well summarized recently by Potter¹. This author states that "64 per cent of patients consult a physician within three months after the appearance of symptoms and in 76 per cent of these a positive diagnosis was made by the family physician within three months after the first visit of the patient." In spite of this relatively prompt action on the part of patient and physician after symptoms had appeared, this author found that 84 per cent of the cases were diagnosed as advanced tuberculosis, 14 per cent were moderately advanced, and only 2 per cent were minimal. Obviously, under these circumstances it is impossible to establish an adequate control policy.

When health departments first undertook to protect children against diphtheria, school clinics were organized, for here large numbers could be readily reached. There was no difficulty encountered in securing the protection of as many as 70 per cent of such children. The prevalence of diphtheria, however, did not materially decrease until the preventive program was advanced to include the protection of the preschool child and infant, for it is among these children that most of the deaths would occur. There is no need of expending effort and money after the damage has been done. Likewise with tuberculosis, we must step up our program so as to find and serve the minimal case.

To do this involves the more effective utilization of facilities which usually are available or can readily be made available in every community. Money may be lacking, however, with state and federal assistance, this handicap can be overcome. As a matter of fact, from the point of view of economics, it must be overcome. In one large midwestern county, two and one-half million dollars of public money is being spent annually

to hospitalize tuberculosis cases. This cares for 2,500 hospital beds—more than twice the annual number of deaths. In the past few years only 13 per cent of cases reported to the health department by the family physician were minimal. When, to this is added the follow up of contacts and school examinations by the health department, the percentage of minimal cases is raised to 20. There are but few American communities which report as high a percentage of early cases. Four out of five cases are already either moderately or far advanced. The average period of hospitalization for the early case is from eight to nine months. The advanced and far advanced case requires twice that period of hospitalization. It is at once apparent that by increasing the percentage of minimal from 20 to 50 the hospital load would be proportionately reduced and the community would save more than a million dollars in annual hospital bills. In other words, much if not all of the money being spent for hospitalization should never be spent. There should be no cause for its expenditure. Finding the early case will reduce the hospital load and expense and save money. The diversion of a fraction of this saving in hospital bills to adequate case finding facilities would be good economy.

By and large, the public is not moved when health workers talk about tuberculosis as a communicable disease caused by a bacillus discovered by Robert Koch in 1882—a disease which is preventable. These facts are fairly well known to the 20 per cent of the population who are health minded. The rest do not care under any circumstances, unless it can be shown in a rather spectacular manner that they are directly involved in the hazard. Health officers must be rather startling in their statements to the public. Be spectacular but not sinful. Do not merely talk about the dangers of tuberculosis but tell the people that we are dealing with a murderer, that we are death fighters engaged in a deadly combat with a vicious foe. Be impressive but not untruthful. Borrow some of the dynamics of the commercial advertiser but do not stoop to false statements. No one may be interested in saving human lives, in reducing the death rate from tuberculosis, in expanding the life span or even in bettering the happiness of our fellow beings, but every one is interested in saving tax money. Spending \$200,000 to save a million dollars annually is impressive. It was on that basis that Detroit so effectively sold its tuberculosis case-finding program that not one word of objection was offered from any source.

Fortunately, in public health work we build our programs on acceptable facts that come to us from the research institutes and centers of learning. We do not deal with philosophical hypotheses, we are concerned with truths that emanate from scientific laboratories. Granted that at times it is difficult to evaluate the effectiveness of a given control procedure, such as a four week isolation period for scarlet fever or the use of the alum picric acid spray for contacts to polio myelitis, but study and experience generally result in reasonable practice. In the case of tuberculosis we have the facts. We know its mode of transmission, that it cannot be controlled by a case-finding program based on symptomatology, that through health education we must arouse an interest on the part of the individual in order that he will seek early medical advice, that we must have the facilities with which to provide the essential services such as diagnosis and hospital care. Correlate this knowledge with the basic statistical facts, with the economic advantage to the community, present your

story through the most influential educational channels in your community, then public opinion will demand reasonable financial support for your program

Concerning the situation in Detroit, an author of national repute wrote a book, the book was read by the owner and editor of a leading newspaper which had long supported public health progress. This resulted in a series of meetings between physicians, educators, business men, manufacturers, newspaper men, public health men and women, and representatives of the public. Out of these sessions grew a program based on a common interest of all in the eradication of tuberculosis. A series of twelve first-page newspaper stories was prepared and published so as to synchronize with

modern technics of preventive medicine—the tuberculin test, the x-ray examination, he will become a very potent factor in the discovery of minimal tuberculosis

Fortunately, in Detroit we have been able to develop our tuberculosis program on the strong foundation of medical participation established in 1928 in our diphtheria prevention work. It will be recalled that since that year all protective treatments have been given by physicians chosen by the family under a plan developed jointly by the Wayne County Medical Society and the Detroit Department of Health, which assures the individual that he will receive the type of service to which he is entitled, at reasonable cost or at no cost if he is financially embarrassed. At the same time the physi-

Map showing areas of high tuberculosis mortality in which intensive case finding work is carried on

radio dramatization. The community was told about the folly of spending public funds for the care of end results in tuberculosis. It was urged that a relatively small sum be spent for prevention. The appeal was reasonable, results were immediate, an additional million dollars was added to the budget of the health department to be used during the next five years to improve case-finding facilities. With the wherewithal at hand, the challenge had to be met.

Most health officers will agree with the statement that the family physician should practice preventive as well as curative medicine in his own office. After all, it is the family medical counselor who sees the early departures from normal health, both physical and mental. It is he who must be prepared to diagnose the early case of tuberculosis. As long as he considers this a disease diagnosed by such symptoms as fever, loss of weight and appetite, night sweats and possibly hemorrhage, he will be of no assistance, but place in his hands the

physician is assured of compensation either from the patient or from the department of health. During the first two years of the diphtheria program the health department paid for two thirds of the services, not because so many people were indigent but because there were many persons who had not learned that diphtheria prevention is a purchasable commodity as essential to the child as food, fuel, clothing or shelter. During the last two years the health department has paid for but 20 per cent of the diphtheria protective treatments known to have been administered. This indicates that the layman has not only learned the value of the service but now appreciates that it should be purchased from the family physician. There has been no decrease in the percentage of children protected during these nine years. The percentage of school children given the protective treatments has remained at a constant level of 70, the percentage of preschool children protected has increased from 30 to more than 60, and it is known

that during the past two years not less than 52 per cent of infants born in the city have been given the protective treatments by the time they have reached the age of 18 months.

Before the inauguration of this program the medical profession was prepared with regard both to the administrative details of the program itself and, what is more important, to the technic of the services that were to be rendered. The same type of approach has been applied to the tuberculosis program, and so important has become this phase of the work that a director of medical relations was appointed several months ago. He gives full time to the problem of seeing that the rank and file of physicians are conversant with the type of service which they are to render. Instead of dealing with a relatively small group of clinic physicians, we are dealing with a large group of cooperating physicians functioning through their own offices. These, in fact, become subhealth centers for the community, from which constantly flows an ever increasing volume of preventive work. The cooperation of physicians

health nurse, fortified with a favorable attitude toward medical participation, has been found an invaluable ally in promoting individual health instruction. It is through her constant contact with families in the home that results are obtained.

In Detroit a determined effort is now being made to find the minimal case of tuberculosis and to provide adequate medical and hospital care for such cases. In 1936 many conferences were held with influential citizens, death fighters, publicists and educators, preparatory to the launching in November of that year of a drive to supplement the conventional services which are common to most modern health departments.

Step by step the entire medical profession was kept informed of the plans, postgraduate conferences were renewed, newspaper articles were featured, radio dramatization was emphasized. Beginning at that time and on each succeeding Wednesday evening a thirty minute broadcast has been given in the auditorium of the Detroit News Radio Station WWJ. The broadcasting auditorium, with a seating capacity for 340, has

been used by the medical profession and other interested groups not only for the radio program but for addresses by distinguished professional men. To a preview, attended by the Surgeon General of the United States Public Health Service, were invited the physicians, that they might see and criticize in advance of formal presentation to the public. Physicians throughout the city urged their patients to read the newspaper articles and tune in on the radio. Agreements were signed by 800 physicians, who thus consented to cooperate with the county medical society and the department of health in this endeavor to discover tuberculosis in its earliest stage. In every instance the public has been urged to seek the advice and service of the family physician, but where there is no physician of choice, a list of cooperating phy-

sicians has been prepared and distributed to the public health nurses. The entire city has been divided into thirty-five areas and there is a list for each district.

When, in the judgment of the cooperating physician the family cannot pay for the tuberculin test or the x-ray examination, the health department provides through its budget a fee of one dollar for the tuberculin test, including the reading of the result. Also for those who give a positive tuberculin test, arrangements are made for referring the patient to one of a group of cooperating roentgenologists, this list being restricted to those who specialize in this field. Again, if financial embarrassment prevents payment for this service, the health department compensates the roentgenologist at the rate of three dollars for each flat plate examination, including a report to the family physician. The family physician again receives an additional dollar for consultation and advice to the patient. Thus it will be seen that for each individual with a negative tuberculin test the cost to the health department is one dollar. For the positive reactor the cost may be five dollars.

That portion of the program which involves the x-ray examination is under the supervision of the Detroit Roentgen Ray Society cooperating with the medi-

Tuberculosis census card, on which are recorded pertinent facts regarding the family unit residing in an area of high tuberculosis mortality.

involves the establishment of postgraduate or refresher courses. These have now been maintained for the past nine years. The health department has an adequate appropriation included in its budget for the support of this postgraduate service. Those physicians who are not wont to attend medical meetings are visited in their own offices. There is every assurance that the program and its technics are thoroughly understood.

The facts, the money and the prepared professional group being at hand the next undertaking is to present the story to the public in such a manner as will result in service for those portions of the population in need of it. The mere presentation of facts is not sufficient, the individual must be stimulated to action, a change in behavior must be established so that he will seek service from his physician. This demands the pooling of all the interests in health education. Every individual and agency, from the family physician and dentist to the teacher, the newspaper editor and the preacher, must be integrated into the program. The tools of health education are too well known to demand elaboration. Health departments are accustomed to employ popular education which includes all means of utilizing the printed and the spoken word. The well trained public

cal society and the department of health. When the examining physician does not provide an x-ray service in his own office, it is agreed that such cases be referred to one of a group of cooperating roentgenologists limited to specialists in this field. In turn, the Roentgen Ray Society has appointed a committee, to which is referred all doubtful and positive films taken either by physicians or by special roentgenologists, and the committee's final judgment is submitted to the examining physician.

In order that there may be provided some measurement of the success of the program, records are essential. Each physician has been provided with a card which he may keep in his own office and in addition to that there are three cards which are mailed to the health department. These double postcards can be sealed and thus avoid any embarrassment by the accidental disclosing of confidential information. The postage on the cards is paid by the department of health and the cards are mailed to the department of health irrespective of whether the patient pays or the physician bills the health department. There are individual report cards for the tuberculin test, the x-ray examination and the final consultation.

Following the special newspaper stories and radio dramas, in December 1936 the city council authorized the department of health to add approximately \$200,000 per annum to its annual budget to be used exclusively for tuberculosis case-finding work. The new appropriations provide for the employment of forty-five additional public health nurses (the total number of health department nurses July 1, 1937, is 430), twelve new stenographers and statistical clerks, two new health educators (to be added to the staff of nine), \$40,000 for tuberculin tests, \$40,000 for x-ray examinations, \$3,000 for postgraduate medical conferences, and miscellaneous items for transportation, maintenance, printing and postage. This program anticipates the supplemental expenditure of a million dollars during the next five years.

In January 1937 the personnel for the new work was engaged and underwent a period of training. By February 1, public health nurses began a house-to-house canvass in areas of high mortality. Even before the start of the field work, as a result of the newspaper and radio publicity, 2,000 tuberculin tests had been recorded by the cooperating physicians. Since February 1 (and prior to May 21) there had been recorded with the health department 33,367 tuberculin tests, of which 7,472, or 22 per cent, were positive. Of this group 5,122, or 69 per cent had completed the x-ray study and in the latter group there had been discovered 242 new active cases of tuberculosis. This means that about 0.75 per cent of the persons examined (at all ages) was found to have active tuberculosis. Of particular significance is the fact that 43 per cent of these new cases of tuberculosis have been classified as minimal.

While it is true that there are many danger spots in tuberculosis, it was decided in the present program to limit the intensive case-finding effort to three definite undertakings. Into every physician's practice come persons with a history and appearance that suggest tuberculosis. They may be considered the suspects for whom an examination is indicated as a possible means of revealing suggested signs of this disease. The tuberculin test will generally establish the presence or absence of infection with the tubercle bacilli. This followed with an x-ray examination of the chest of the

positive reactor, will reveal in detail much that cannot be detected by physical examination alone. Then a special search should be made of the contacts to the active case of adult type tuberculosis. Household contacts come under immediate suspicion on two accounts—first, if the person already found has a positive sputum one or more of the other members of the household may have acquired tuberculosis from him, second, if the person already found does not have positive sputum, one of the other members of the household may be the source of infection and should therefore be detected. There are certain groups in the community who may be regarded in almost the same light as household contacts such, for instance as residents in those districts of the city in which the tuberculosis mortality is high. These areas should be well known to the health department and information regarding them should be made available to all cooperating physicians. Thus the immediate objective has been to reach these three groups: first, those in the practice of the physician whom they suspect of being tuberculous, second, household contacts of definitely diagnosed cases, and, third, persons residing in areas in which the mortality from tuberculosis is excessively high.

Card on which the physician reports the tuberculin test to the health department. Somewhat similar cards are used to report x-ray examinations and final consultation.

While it is granted that there are other important groups, such as school children of a selected age or grade, employees in industrial plants, food handlers, prenatal cases, diabetic patients and those who are recovering from acute infections, it was deemed advisable to undertake the case-finding work first in those groups in which the largest number of suspects and cases would be likely to be found. Within two months after the inauguration of the intensive educational work by the public health nurses in the visited group of families in the area of high mortality, 30 per cent of the Negroes (including all ages) had gone to their physician and reports had come through to the health department on the results of the tuberculin tests. Proportionately, only one-third as many white persons had responded, that is, 10 per cent of the members of the families visited. It is believed that these results obtained in the brief period of two months show a most encouraging response.

SUMMARY

It may be said that the control of tuberculosis is by no means an accomplished fact, it is especially unsound to permit the continued financial burden on our communities due to tuberculosis when the facts concerning its control are so complete, the facts should be pre-

sented to the public and the necessary financial support obtained, the habits of persons should be changed so that they will seek medical advice at a time when an early diagnosis can be made, the required diagnostic service can be provided by a group of qualified cooperating physicians serving through their own offices under a plan which functions through the organized community, especially the medical society and the health department

3919 John R Street

ABSTRACT OF DISCUSSION

DR ESMOND R LONG, Philadelphia The Detroit plan is now well known and it is apparent from the report of Drs Vaughan and Douglas that even within the short time since its inauguration it has already achieved a definite measure of success. The authors have brought out two important facts: (1) that the majority of cases of tuberculosis are in an advanced state when first detected and (2) that the disease is almost symptomless in the minimal stage when its detection would most readily be followed by cure. No program for the control of tuberculosis is adequate if it fails to take account of the fact that the disease is so nearly symptomless at its onset. What is commonly called its onset, the symptom complex characterized by a cough, fever and night sweats, is not the onset but a stage of active progression. Because of these facts, the usual methods of private medical practice are not sufficient. The patient will not seek the physician, because he is not aware that anything is wrong, therefore the physician must seek him. The problem is complicated by various questions of economics, medical ethics and relationships between the practicing medical profession and the official departments of health. Since, however, in the last analysis, our function as physicians is the preservation of health in the population, some way must be found to cut through all such complications. The Detroit plan seems to have been eminently successful in its dual task of case finding and harmony of medical relationship. Case finding, largely through the intensive educational campaign carried on by the National Tuberculosis Association during the last fifteen years, has become the prime objective of tuberculosis divisions of health departments. I think most of us would reverse the order of preference as given by Vaughan and Douglas and say first isolate the infectious case and, second, find the minimal cases. Basic standards exist for determining fairly closely the number of open cases in any large community. They are in the proportion of about three to each annual death from tuberculosis. We actually know and have some sort of supervision over about half of the open cases in the country today. A quick and successful campaign to find the other half will rapidly cut down the supply of new cases, which may be thought of as a yearly crop sown by the old cases. Few would quarrel with the selection of three fields for intensive case finding as given by Vaughan and Douglas, however, sooner or later we must attack the problem of tuberculosis in industry. Notable success has attended case finding campaigns in the schools and colleges, but the age period is too early to reach the bulk of tuberculosis cases. The work of the medical staff of the Metropolitan Life Insurance Company furnishes a model for what might be done for later ages. Statistics show a concentration of tuberculosis in the unskilled trades.

DR HAVEN EMERSON, New York Some of the best lessons in the field of public health are presented by this report of the Detroit method. The tuberculosis problem remains now, as it always has been, in the office of the private practitioner, and this method of putting on him the responsibility of finding infected persons, as well as finding sick persons, is a logical step. Finding one case of tuberculosis by the making of 111 tuberculin tests is, to my mind, an inexpensive undertaking for any health department. For every 111 intradermal tuberculin tests, one case of the disease has been found in Detroit, and of the cases found, 44 per cent are minimal. Every person in the community has a right to know whether he or she is infected with either tuberculosis or syphilis and, if infected, what was the source of the infection. Widespread use of the Wassermann and Kahn tests and of the tuberculin test is begin-

ning to give a scientific measurement of the prevalence of infection, and the oftener these tests are made the nearer we are likely to get to the source of infection. If we can discover infection in the preschool child, we shall be just twenty years ahead of the time when the adult in industry develops the disease. Whatever may be done to discover young adults sick with tuberculosis in industrial life, there remains the job of finding the child as soon as practicable after it has been infected. When an attempt is made to trace the source of infection in a person of 25 who develops open tuberculosis in industry, there are so many uncertain factors of family and other contacts that one is baffled by time and circumstance. The lesson that Vaughan and Douglas have offered is that it is possible to save on the cost of treatment by heavy investment in the discovery of infection. I believe that economy as well as self-interest points directly to the following of the Detroit method, and that the best message that can be given to the members of the American Medical Association is that every physician should persuade his patients to be intelligently curious about their infection with the tubercle bacillus or freedom from it and, if they prove to be infected, to be unsatisfied until the probable source of their infection is traced.

DR E R HAYHURST, Columbus, Ohio For many years tuberculosis was the leading cause of death among the gainfully employed. It stands second to heart disease today. The papers presented in this section have emphasized tuberculosis in relation to the Negro, to industry and to fatigue, but thus far it has not been possible to evaluate industrial fatigue. The physiologists may some day evolve a method of detecting fatigue and of separating its manifestations from those of other conditions, following which there may be a measuring stick for industrial fatigue. While not dismissing the great importance of infection and cross-infection, I think the relation of tuberculosis to fatigue is very prominent. Another factor which is notable with industrial workers is that they do not know or appreciate protective diets, and they are beset with a confusing commercialized propaganda regarding diet. There is a tremendous field here for education which might be worked out by such a scheme as Detroit is using to build better resistance in the industrial population.

DR J I LINDE, New Haven, Conn Having practiced pediatrics more than twenty years, I should like to make some statements. One is that the authors have recognized the fact that the private physician is the backbone of public health. I don't know who made that statement, but they have recognized that. The second is that Vaughan and Douglas have given to the private physicians the kind of state medicine they like.

DR A E JAFFIN, Jersey City, N J I am sure we all feel that the ideal arrangement would be for every physician to become a public health officer, at least as far as tuberculosis is concerned. In the northern part of New Jersey, where I have had the opportunity for twenty-odd years of being connected with tuberculosis clinics, we have faced that problem. Do the authors expect to get the majority of doctors actively and continuously interested in cooperating as they wish them to? Can the public be expected to remain health conscious long enough to be retested with tuberculin or roentgenographed more or less regularly when necessary? Those who are negative this year may not be negative next year. Will there be a repetition of this more or less constant survey? How is the teen-age problem met in Detroit, particularly in the high school group? We felt that the most rapid approach for the sake of the greatest good would be a survey of the teen age by testing our high school children in Jersey City, some 17,500. After getting consents from 90 per cent, we did 15,000 tests and all those which were positive to tuberculin were roentgenographed by the rapid paper method. The films are now being read. In this undertaking we had the cooperation of the county medical society. A number of men volunteered to take the necessary training to qualify them for testing. They were paid out of funds provided by the Tuberculosis League from Christmas seal sales while the county and city paid for the films. Some thirty-six men responded for this work. Less than 10 per cent of the county physicians volunteered or showed an active interest in this undertaking—a rather small percentage. We found great difficulty in getting members c

our county society sufficiently interested in undertaking this Detroit plan, and I was very much interested in hearing what Vaughan and Douglas had to say. What will the solution of the problem be so far as the teen-age children are concerned, in whom I feel lies the most fertile soil for the early recognition of the future cases of active pulmonary tuberculosis?

DR. L. M. ROHR, Brooklyn. In Williamsburg-Greenpoint we have tackled this tuberculosis problem in a very different way because of a very small budget, 51 cents per capita. We haven't obtained the wonderful cooperation Vaughan and Douglas speak about. We have organized a Chest Consultation Service. We invite the private physician to use our tuberculosis service as his own. We give his patient a complete physical examination, x-ray service, fluoroscopic service and sputum examination. The examination is confidential, and he receives a confidential communication by mail. The county medical society utilizes and approves this method. We use the county society to notify the physician that this service is available, and it is surprising the great number of cases that are sent to us. Ten per cent of the cases referred to the Chest Consultation Service are found to show some stage of tuberculosis, and about 15 per cent of those cases are in the minimal stages. The private physician still needs much education. We are therefore using our tuberculosis services as teaching centers. Our tuberculosis clinics are now open to groups of physicians, six or eight at a time. We give them about three months' intensive instruction, and then to some of the most satisfactory we offer clinical positions in the health department. Through that interest in tuberculosis work in the borough of Brooklyn we have been able to organize the Brooklyn Thoracic Society. We are doing all sorts of things to interest the private practitioner in our work and to get the cases early. The authors present a very fine, utopian picture for the private practitioner. We have in a small measure made the private practitioner's office a health center. In Williamsburg-Greenpoint Health District, we found that only about 40 per cent of the children had been immunized against diphtheria. Through the efforts of the Kings County Society we interested the private practitioners of the district, and in 1935 the private practitioners of the district immunized 13,000 children. Our death rate became nil in 1936. Our case rate was down to 46. Previously it had been 130 cases, with four deaths.

DR. HENRY F. VAUGHAN, Detroit. May I say to Dr. Rohr I do not believe there is any city but that must do something of this character, irrespective of whether one is spending 51 cents or a dollar per capita. The money must be found somewhere, otherwise large sums of money will continue to be wasted in the end results of tuberculosis. In answer to Dr. Long I wish to state that, being a public health man, I think we need to find the minimal case first. We have an Industrial Hygiene Division, under the able direction of Dr. C. P. McCord, and the industrial program is operating in cooperation with this tuberculosis case-finding program. But let us not lose sight of the fact that everybody in Detroit is interested in industry. We have nothing there but industry, and the most economical thing we could do was to deal with the hot spots, readily isolated from the rest, where most of the tuberculosis would be found. I could list twelve or fourteen different classes of persons who need special attention, prenatal cases, the diabetic, persons recovering from some acute infectious disease, industrial workers, the food handlers and children of the teen age. These are all important. We took the three classes (1) contacts, (2) suspicious cases and (3) individuals residing in areas of high mortality as being the most productive of new cases of tuberculosis and the most rapid way of isolating the infectious case from the community. We should have emphasized, as we did in the complete paper, that there is nothing in the program which detracts from our usual conventional procedures. This program is not a substitute for what the health department has been doing for years. We are still tuberculin testing annually 20,000 school children through the local tuberculosis association. The clinics are being operated and are used for teaching purposes. We must have such teaching facilities or we could not provide instruction for cooperating physicians so in this respect our plan is the same type of program referred to by Dr. Rohr as existing in New York.

I feel that the evidence brought forth by our diphtheria program shows that the interest of the physician can be continuous, and as for the interest of the public, as a matter of fact, only 18 per cent of the diphtheria immunizations are being paid for by the health department. This indicates the willingness of the public to cooperate, and the constant increase in the number of children immunized at the susceptible age would indicate likewise. As far as the physicians are concerned, there is no question about their wholehearted cooperation.

SYPHILIS IN RELATION TO THE PREVENTION OF BLINDNESS

A STUDY OF 100,000 CASE RECORDS

CONRAD BERENS, M.D.

AND

JACOB A. GOLDBERG, PH.D.

NEW YORK

According to recent statistics,¹ syphilis accounted for 53 per cent of the blindness among 2,702 children in schools for the blind. This study indicated that syphilis is probably responsible also for a large proportion of the blindness now classified as congenital or hereditary. Other investigators² have determined that blindness among pupils in schools for the blind and among persons applying for pensions for the blind is attributable to syphilis in percentages varying from 34 to 15. Cowan and Sinclair³ reported that among 6,000 applicants for pensions for the blind in Pennsylvania, 566 eyes, or 94 per cent, were affected with syphilis. In a recent communication, however, Cowan⁴ stated that this estimate is low because it represents merely the cases in which the examiner stated that syphilis was an etiologic factor, whereas, to cite only one source of possible error, many cases of interstitial keratitis were etiologically undiagnosed.

A number of studies relative to the incidence of syphilis among patients suffering from various types of eye diseases have been made. Authoritative data have been presented to indicate the seriousness of syphilis as an etiologic factor in such diseases. However, information is not available from the study of a large series of cases concerning practices in the diagnosis, treatment and follow-up of patients who have syphilis or who may acquire syphilitic eye lesions. These practices include routine serologic tests for syphilis, follow-up of patients with eye disease who have positive Wassermann reactions, examination of immediate relatives, especially husbands, wives and children, of patients with evidence of syphilis, and the use of accepted methods of treating syphilitic eye diseases or eye diseases complicated by syphilis. This study was prompted by the desire to obtain such data so that the number of cases of blindness and marked diminution of vision among persons who have acquired or congenital syphilis might be reduced.

ORGANIZATION OF THE STUDY

To carry out this investigation, a special Committee on the Study of Syphilis and Eye Diseases was organized.

Read before the Section on Ophthalmology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1937.

lar serologic tests on patients with eye disease, (3) to determine minimum social service and follow-up requirements, (4) to help in establishing standards for procedures at eye clinics and (5) to standardize the treatment of syphilitic eye diseases.

In the pursuit of these studies, certain working objectives were set up. These were as follows: (1) to study the method in which records are kept at various eye clinics in New York City, with special reference to syphilis and complications involving the eyes, (2) to analyze the material recorded in the clinical records, (3) to determine whether the serologic tests for syphilis and other laboratory tests are routine measures in cases of eye diseases that may be caused by syphilis, (4) to evaluate the procedures followed in caring for patients with eye disease who have positive Wassermann reactions, (5) to learn whether clinics utilize sufficient follow-up personnel in such cases and (6) to collect the statistical material necessary to determine the percentage of the various eye diseases which may be caused by syphilis.

METHOD OF STUDY

In carrying out this study of syphilis and eye diseases, the records of five important eye institutions in New York City were analyzed and tabulated. The total number of records studied was over 100,000. Records of patients were examined in order that we might obtain the following information: (1) personal history in relation to syphilis, (2) family history, (3) clinical observations, (4) laboratory observations, (5) syphilitic manifestations of the eye, (6) diagnosis, both on admission and on discharge, (7) social

service and follow-up for the eye condition and for the syphilitic condition, (8) disposition of the case, and (9) effect of syphilitic treatment on the eye condition.

The records were found to be incomplete as well as inaccurate. In 1923 a special study⁶ of the medical histories of ten representative ophthalmologic institutions in New York City also demonstrated serious deficiencies in the records. The history was recorded in only 55 per cent, a tentative or final diagnosis in 68 per cent, the treatment in 76 per cent, the vision in 78 per cent, the refraction in 45 per cent and examination of the muscles in 0.44 per cent.

In seeking data on syphilitic manifestations in the eye from a study of 100,000 records, we placed special emphasis on cases in which the following diagnoses⁷ were indicated: (1) iritis, (2) iridocyclitis, (3) retinitis, (4) optic neuritis, (5) choroiditis, (6) optic atrophy, (7) ophthalmoplegia, (8) Argyll Robertson pupil and (9) interstitial keratitis, as well as other diseases. A special form was prepared for this study.

RESULTS OF THE STUDY OF 100,000 CASE RECORDS

The summary of approximately 100,000 case records shows that a total of 5,969 patients, or about 6 per cent, presented diagnoses which were classified by the special Committee on the Study of Syphilis and Eye Diseases as possibly having syphilis as an etiologic factor. However, of the 2,237, or 37.5 per cent, who were given Wassermann tests, 444, or 19.9 per cent, had positive reactions.

Since the method of keeping records varied widely in the five institutions studied, only the most general conclusions may be drawn. The results of the study may be stated briefly in the order of their appearance on the survey form.

Personal Histories.—The personal histories were inaccurate, with meager information concerning syphilitic lesions and the amount of antisyphilitic treatment that patients received. However, our study shows that the full term stillborn children of the patients numbered forty, and the premature stillborn children nine (table 1).

Family Histories.—The family histories furnished inadequate information regarding the presence of syphilis in other members of the patient's family. Also,

TABLE 1—Family and Personal History of Patients Who Had Syphilitic Eye Lesions

	Number of Patients
Full term stillborn children of patients	40
Premature stillborn children of patients	9
Premature stillborn children of patients' mothers	7

evidence of neurosyphilis, for example, tabes dorsalis or dementia paralytica, was not recorded in a sufficient number of cases. The statistics in table 1 indicate that the wives and mothers of syphilitic patients gave birth to thirty-four full term stillborn children. Premature stillborn children were recorded in these families twelve times, syphilitic insanity twice and death attributable

⁷ Tabulation of diagnoses was made after consultation with an advisory committee representing the National Society for the Prevention of Blindness, the American Social Hygiene Association and the Committee on Syphilis and Eye Diseases.

⁵ Members of the subcommittee are Drs. John H. Dunnington, Henry R. Skeel, Francis W. Shine, Jacob A. Goldberg (secretary) and Conrad Berens (chairman).

to syphilis thirteen times. Table 1 likewise shows that syphilis was present in the entire family in twelve instances. When these observations are considered in relation to the estimate of Lewis⁸ that from 50 to 75 per cent of the syphilitic children born of infected women acquire serious diseases of the eye and the statement of Holloway⁹ that sooner or later definite ocular evidence of syphilis is apparent in 75 per cent of congenitally syphilitic persons, syphilis assumes greater significance as a factor in blindness.

The great importance of the treatment of syphilitic pregnant women was stressed by Paley,¹⁰ who studied 617 women who were treated with neoarsphenamine and bismuth compound during pregnancy. The results showed that adequate antisyphilitic therapy during pregnancy greatly reduces the number of living syphilitic babies, miscarriages and stillbirths and the infant mortality in the first two months of life. It was definitely proved that antisyphilitic therapy during pregnancy is effective regardless of the duration of syphilis in the mother. The effect of syphilis in the father was also determined, and the statistics showed that when the father also was syphilitic the incidence of syphilis in the children was higher.

One of us¹¹ made a study of 653 pregnant women in seven antepartum clinics in New York City. Only 22.5 per cent were treated before the fifth month of pregnancy. The antisyphilitic treatments administered were possibly too few in number, as 36.7 per cent of the women were given five treatments or less and 56.3 per cent nine treatments or less. In the cases in which complete records were available, there were 426 normal births and forty-five fetal deaths. The early treatment of prenatal syphilis will undoubtedly result in saving lives, in reducing various manifestations of late syphilis, especially blindness, and in preventing congenital syphilis from affecting many children.

General Physical Examinations in Patients with Syphilitic Eye Lesions.—Although there were practically no records of clinical observations in two institutions, it is noteworthy that a summary of the records of the remaining three institutions shows that meningovascular syphilis was present in twelve cases, congenital syphilis in fifty-one, tertiary syphilis in twenty-four, tabes dorsalis in fifteen, secondary syphilis in nine and primary syphilis in nine. Seven patients gave evidence of cerebrospinal syphilis. If more general physical examinations had been recorded, the relationship of cause and effect between syphilis and eye diseases could have been more completely studied.

Laboratory Examinations.—The record of Wassermann tests made on patients who were classified as having eye lesions probably of syphilitic origin indicates that only 2,237 (37.5 per cent) were given the benefit of a serologic test for syphilis. Of this number 444, or 19.9 per cent, were found to have positive Wassermann reactions (table 2).

Syphilitic Manifestations in the Eye.—Data regarding the diagnosis and examination of the eye lesions were often inaccurate and insufficient. However, in our study the largest percentages of positive Wassermann reactions were recorded for patients with the following diagnoses: interstitial keratitis, 53.8 per cent, kerato-

iritis, 50 per cent, Argyll Robertson pupil, 41.7 per cent, optic neuritis and papillitis, 20 per cent, iritis and iridocyclitis, 15.4 per cent, uveitis, 14.2 per cent, and choroiditis, 12.4 per cent.

Serologic tests for syphilis, even in cases in which the eye disease listed was most likely to be etiologically related to syphilis, were not made as a matter of routine in any of the five clinics studied. The percentage of serologic examinations varied from 22.6 to 78.8 for the group of eye diseases in which syphilis might be the cause. In one clinic only 51.6 per cent of the patients with interstitial keratitis were given a Wasser-

mann test. In the clinic presenting the second highest record of serologic tests, 100 per cent of the patients with interstitial keratitis were tested serologically. Of patients with optic atrophy 94.7 per cent had Wassermann tests. The record for serologic examinations in cases of chorioretinitis was 92.6 per cent, in cases of retinitis 90.9 per cent and in cases of iritis 87.8 per cent. In the clinic which achieved the highest total percentage of serologic testing, 78.8 per cent of all patients with eye disease of probable syphilitic origin were given serologic tests for syphilis.

Gratiot¹² expressed the opinion that Wassermann tests should be made in all cases of disease of the eye in which syphilis may be a causative factor. He reported a positive Wassermann reaction in 20 per cent of the cases of disease of the cornea, in about 38 per cent of the cases of iritis and in thirty-one of forty-

three cases of primary atrophy of the optic nerve, in ten of which the condition was congenital

In table 3 the number of positive and negative Wassermann reactions in the families of the syphilitic patients under consideration is recorded. Though these data are incomplete, they are at least suggestive of the conditions existing in the families of syphilitic patients.

Social Service and Follow-Up—The lack of recorded data rendered it impossible for us to analyze completely the social service and follow-up system. For example, in one institution, in which 145 patients had positive Wassermann reactions, there was no record of a follow-up service in 132 cases. In another institution, with 134 patients, no follow-up was recorded in fifty cases. In still another, with forty-one patients, no follow-up was recorded in fifteen cases. In the institution presenting the best record only eighteen of 100 patients had not been followed up.

Although the importance of social service in relation to syphilis in eye clinics has long been stressed,¹³ the financial support necessary to provide for this service is not available to all institutions. The problem is economic as well as social. The contribution toward effective prevention of syphilis of only a fraction of the money now expended on the support of syphilitic persons would markedly decrease the number of syphilitic tragedies which terminate in blindness. The institution of adequate social service and active follow-up work in all hospitals and clinics would insure completion of treatment so that complications involving the eyes which might result in blindness could be prevented.

SUMMARY

We have pointed out that, although the importance of syphilis in the causation of certain eye diseases is recognized, little information is available from a study of a large series of cases concerning clinical practices regarding the diagnosis, treatment and follow-up of patients who have eye lesions that may be caused by syphilis or who have relatives who may be syphilitic.

These data are important if better methods of attacking the problem of syphilis and preventing blindness are to be instituted.

Approximately 6 per cent of the 100,000 patients in the five institutions were reported as having eye lesions which might have syphilis as an etiologic factor. Data in relation to the personal histories, family histories and previous medical histories were generally inaccurate and insufficient. However, in spite of this, our study revealed that the full term stillborn children of these patients numbered forty and the premature stillborn children nine. It was found that in twelve instances syphilis affected the entire family and that thirteen deaths in the patients' families had been caused by syphilis. It was also shown that wives and mothers of syphilitic patients had given birth to thirty-four full term stillborn children and twelve premature stillborn children.

Previous medical histories and clinical observations in cases of syphilitic disease were inadequate, for congenital syphilis was recorded in only fifty-one cases and tertiary syphilis in twenty-four, while tabes dorsalis was observed in fifteen. Only 37.5 per cent of the patients in whom syphilis may have been an etiologic factor were given the benefit of serologic tests. Approximately 20 per cent of the Wassermann reactions in these cases were positive. Serologic tests were not made as a matter of routine in any of the clinics on the patients who had eye lesions that were considered to be of syphilitic origin. The percentage of serologic examinations made varied from 22.6 to 78.8.

It is cause for serious consideration that in one clinic only 51.6 per cent of the patients with interstitial keratitis were subjected to Wassermann tests. This is particularly important in view of the fact that 53.8 per cent of the entire group of patients with interstitial keratitis had positive Wassermann reactions and that 50 per cent of those with kerato-iritis showed positive reactions. The next highest percentage of positive Wassermann reactions, 41.7, was recorded for patients with Argyll Robertson pupils. It is important that 14.2 per cent of those with uveitis and 15.4 per cent of those with iritis and iridocyclitis had positive reactions. As would be expected, the percentage of positive reactions in the group with choroiditis was lower, only 12.4. It is most unfortunate that more Wassermann tests are not made in families of syphilitic patients because, although only 216 tests were made, 160 of the reactions were positive. The highest percentage occurred in mothers, approximately 37.

The great importance of the treatment of pregnant women has been clearly demonstrated by Paley,¹⁰ who showed that adequate antisyphilitic therapy during pregnancy greatly reduces the number of living syphilitic babies, miscarriages and stillbirths, as well as the infant mortality in the first two months of life.

One of the most serious failures in several of the clinics, from the standpoint of the prevention of blindness, was in the social service and follow-up work. Only thirteen of 145 patients with positive Wassermann reactions were followed up in one clinic. No doubt the financial factor is an important cause for the failure to provide social service and follow-up work. However, after long study of this subject,¹⁴ it is our conviction

that much of the blame must be borne by physicians for their lack of interest in or lack of complete understanding of the importance of this work

CONCLUSIONS AND RECOMMENDATIONS

A study of 100,000 records shows that 5,969 patients (approximately 6 per cent) had eye lesions which may have had syphilis as an etiologic factor. However, in many cases the diagnoses were omitted from records and the clinical observations were so incomplete that accurate diagnoses could not be made.

From this study of syphilis in five eye institutions, the following conclusions and recommendations seem justified:

1 The personal histories, although inaccurate and lacking in detail, showed that the patients with syphilitic eye lesions gave birth to forty-nine stillborn children. In order that more of these valuable data may be obtained, it is recommended that personal histories be more accurate and detailed, special emphasis being placed on the history of syphilis, genital lesions, cutaneous lesions and ulcers and on the exact amount of treatment received and where such treatment was given.

2 The family histories were inaccurate but the small group recorded showed that the relatives of patients had forty-six stillborn children, that syphilis affected the entire family in twelve instances and that there were two cases of syphilitic insanity and thirteen syphilitic deaths in the patients' families. It is recommended that the family histories of patients with eye lesions which may be caused by syphilis include data regarding syphilis in the father, mother, children and other relatives. A record should also be made of a history of dementia paralytica, tabes dorsalis and other syphilitic nervous diseases. It is important to record the cause of death of members of the patient's immediate family.

3 The clinical, medical and neurologic data were most incomplete, as congenital syphilis was recorded in only fifty-one cases, meningovascular syphilis in twelve, tertiary syphilis in twenty-four, tabes dorsalis in fifteen, secondary syphilis in nine, primary syphilis in nine and cerebrospinal syphilis in seven. It is recommended that more careful attention be given to the medical and neurologic data in cases of syphilitic eye diseases.

4 Laboratory examinations showed that Wassermann tests were made in only 2,237 (37.5 per cent) of the 5,969 cases in which the diagnosis was an eye disease of possible syphilitic origin. Of the patients tested, 444, or 19.9 per cent, had positive reactions. It is recommended that a Wassermann test be performed on all patients with eye lesions possibly syphilitic.

5 The data regarding diagnosis and examination of the eye lesion were often inaccurate and insufficient. It is recommended that greater care be exercised in recording the exact diagnosis on admission and discharge from a hospital or clinic.

6 The social service and follow-up work in relation to the eye disease and to syphilis showed an appalling lack of thoroughness. Although all the institutions had social service departments, only a small percentage of the patients with positive Wassermann reactions were followed up. In one institution, only thirteen patients of 145 were rendered this service. Therefore, it is recommended that all patients with positive Wassermann reactions who have syphilitic eye lesions be followed up and that a study of the patients' relatives also be instituted.

7 The great importance of social service work in the prevention of unnecessary blindness is evident from this

study, but recorded data were incomplete. It is recommended therefore that the social service data indicate the reference of the patient to other hospitals or clinics or to a physician and the final discharge.

8 Notes on progress often failed to indicate the result of antisyphilitic treatment from the point of view of the eye or from the serologic standpoint. Therefore, it is recommended that these data be more complete.

If much unnecessary blindness caused by syphilis is to be prevented, the recommendations embodied in this study must not only be considered seriously but must be carried out in a systematic manner in hospitals and clinics. Especial attention must be given to the follow-up of individual patients and their families.

35 East Seventieth Street

ABSTRACT OF DISCUSSION

DR E. V. L. BROWN, Chicago. These records are characterized by the writers of this paper as inadequate and inaccurate. Some 6,000 cases of the 100,000 were diagnosed as syphilitic, but a Wassermann test had been made in less than half. Notes concerning the primary, secondary and tertiary nature of the syphilis present were lacking in 97 per cent of the cases, and histories of syphilis in the patient or his family were lacking in 98 per cent. Eye examinations were likewise often inaccurate and insufficient. Interstitial keratitis was diagnosed in 240 cases, yet the fact that the Wassermann reaction was positive in only 54 per cent of them leads one to suspect that there were actually only about 150 real cases of interstitial cases in the group, because Igersteiner gives the Wassermann reaction as positive in 91.9 per cent. The conclusion is hard to escape that a large number of the cases of interstitial keratitis were diagnosed by these dispensaries when they were not interstitial keratitis at all. There is no reason to believe that the rest of the work was any better, and the records cannot by any stretch of the imagination be considered as a contribution to our knowledge of the subject of syphilis in relation to the eye as given in the title of the paper. This is not the fault of the authors, who apparently recognized this fully and placed a goodly part of the blame on the lack of funds for social service. Four or five clinics had social service but it was spread out pretty thin, for although it was supposed to cover matters of attendance, treatment, discharge and reference to other hospitals, to the department of health, to the department of hospitals, to a state hospital or to a private physician to record syphilis as a cause of death, even a single such note was found recorded in only 8 per cent of the cases. In one line the authors do get at the heart of the matter for they say "much of the blame must be borne by the physicians." But they offer no remedy or suggestion of any kind. In my opinion the reason for poor records is to be found in the widespread failure to recognize the dispensary as the crux, the heart, of the eye clinic, and the failure of the chief of service and, in particular, the head of the department to spend a minimum of three fourths of his time in the dispensary and secondly to give a good three fourths of the eye surgery to attending men of middle rank on the staff. Too often he takes it all himself or gives it to the intern in unnecessary amount. If the competent and hard-working men in the middle rank of the staff are properly worked with and rewarded, they will do good work and make good records. If they are not given proper consideration, there will not be good work, good records or any other good activity in the dispensary. The condition is countrywide, worldwide. Every one knows the London, Paris, Vienna, Chicago, Boston clinics. It is certainly not peculiar to eye work. This paper makes the situation clear.

DR JOHN GREEN, St. Louis. This study shows that about 6,000 patients had ocular conditions which might have been caused by syphilis. It is therefore rather startling to note that only 2,237, or 37.5 per cent of these patients were investigated serologically and that positive reactions were obtained in only 444 or 19.9 per cent. The inference may be drawn that the clinicians did not think it worth while to have the Wassermann test made unless the clinical evidence pointed very strongly to

syphilis as the etiologic factor. The investigation disclosed many glaring defects which are probably common to clinical services throughout the country—incomplete and inaccurate personal and family histories, meager information on lesions and treatment, and entirely inadequate social service and follow up. The authors quote Lewis and Holloway, who believe that from 50 to 75 per cent of syphilitic children develop serious diseases of the eye. This estimate is, in my opinion, quite accurate. From 1916 to 1919 I made a study of 100 syphilitic children from the pediatric clinic of the Washington University Dispensary and the wards of the St. Louis Children's Hospital. It is believed that these 100 cases fairly represent the types of hereditary syphilis seen in a pediatric service and that the number and kinds of ocular complications are what might be expected in such a group. The clinical diagnosis was confirmed in every case by at least a two plus blood Wassermann reaction. Seventy-four of these children presented definite pathologic conditions in one or more of the ocular tissues or some derangement of ocular function. As adequate treatment of syphilitic women will almost certainly result in the birth of healthy babies, the means are at hand to eradicate all syphilitic eye diseases in infants and children. By this one means alone the incidence of blindness due to syphilis would be reduced 50 per cent. To designate an eye disease as having a syphilitic origin in every case in which the serologic reaction is positive is a grave mistake, but it is equally reprehensible to neglect to have a blood Wassermann test made in certain cases in which the clinical manifestations do not certainly indicate syphilis. It is indeed amazing that in the ocular disease that almost invariably has a syphilitic basis, namely, interstitial keratitis, a positive Wassermann reaction should have been found in only 53.8 per cent. This percentage is so much at variance with ophthalmologic opinion that, with rare exceptions, interstitial keratitis occurring in children is of syphilitic origin that it must point to the neglect of the serologic test in too large a number of cases of this disease.

DR. LOUIS LEHRFELD, Philadelphia. A survey on syphilitic optic atrophy has just been completed at the Wills Hospital, Philadelphia. A statistical investigation was made of 600 cases of syphilis affecting the optic nerve during a ten year period. The objective of the survey was to find out what happens to the eyesight of syphilitic patients who already show signs of involvement of the nervous system, and to ascertain how effective present methods of treatment might be. The most important conclusion of the survey is that the present day treatment of syphilitic patients having optic nerve involvement is entirely unsatisfactory so far as improvement of vision is concerned. The only appreciable difference among the treated and the nontreated patients with syphilis who have optic nerve degeneration is that the nontreated patients became blind in five years while the treated patients became blind in eight years. Of a group of 350 patients, 250 were white and 100 Negroes. The preponderance of syphilitic optic atrophy among the white patients compared with the Negroes, in whom syphilis is five times more prevalent, may be a basis for suspecting that present methods of treatment may precipitate early optic atrophy, while those who are lax in receiving treatment, particularly Negroes, are less likely to develop optic atrophy. There is no doubt in my mind that early treatment of syphilis affecting the ocular structures should be instituted to save sight. There is also no doubt in my mind that the present methods of using arsenicals must be revised if we wish to reduce the percentage of blindness from syphilitic optic atrophy. At the present moment the best method of preventing blindness from syphilis is to prevent the disease itself and not to place full reliance on the treatment of the disease.

MR. LEWIS H. CARRIS, New York. Though I can't discuss this paper from the scientific standpoint, on behalf of the National Society for the Prevention of Blindness, I am grateful to this organization for presenting this subject. Two things seem to me to be clearly shown: first, the need for improvement in the clinical service and second, the importance of the social service follow-up work, in which we have been concerned. It is gratifying to note the progress being made in public health teaching with regard to the prevention and early treatment of syphilis. By getting at the heart of this problem eventually there should be few cases that need the eye physician's help.

DR. CONRAD BERENS, New York. Dr. Brown's discussion, particularly his statement with regard to social service, is interesting. I feel that social service is exceedingly important and believe that more social service is needed. For example, in one institution in New York which has an eye and ear service, one, two and at times three workers care for 6000 new admissions a year. Therefore, little time can be devoted to the careful study of any particular group of eye patients. As a matter of fact this amount of social service work does not effectively and efficiently take care of our glaucoma patients alone. I agree with Dr. Brown that this paper is not a contribution to the study of syphilis except possibly as it relates to the prevention of blindness. Dr. Brown mentioned what I consider a vital point—the question of the importance of the clinic in the prevention of blindness. Those associated with the National Society for the Prevention of Blindness have long believed the clinic to be one of the most important factors in the prevention of blindness movement. I agree with Lehigh that we must not think so much of how to treat the disease, particularly disease of the optic nerve, but if we can only prevent the disease from developing we then can say that we are fulfilling our most important function as ophthalmologists. Dr. Green has raised another important point. He makes a point of having the cases studied by one particular physician in each clinic. We are coming more and more to the realization that if we hope to have efficient service in treating certain eye diseases, for example, glaucoma, syphilis and tuberculosis of the eye, we must develop certain physicians in our clinics who will more efficiently and scientifically care for these particular cases. Moreover, we must have adequate social service work in conjunction with this specialized medical work.

THE INCIDENCE OF OPERATIONS FOR GOITER IN SOUTHERN MICHIGAN

EFFECT OF IODIZED SALT AFTER TWELVE YEARS'
GENERAL USE

ROY D. McCLURE, M.D.
DETROIT

There is no need to discuss here the now well known deleterious effect of a diet deficient in iodine. To Marine and his associates for their scientific discoveries, their stimulation of other workers and the dissemination of this newer knowledge is due all credit. Plummer, too, should be mentioned in any clinical talk on thyroid and iodine, as he scientifically demonstrated the early marked improvement, temporary though it may be, of patients with hyperthyroid disease from iodine administration.

Michigan lies in the center of the Great Lakes endemic goiter belt, one of the large, though not the most severe, endemic goiter areas. In these great areas both food and drinking water are known to be deficient in iodine. This deficiency in iodine is not observed uniformly throughout the so-called goiter belt. At Mount Clemens, Mich., 26 per cent of the children had enlarged thyroids, while at Romeo, Mich., 12 miles distant, 75 per cent of the children had enlarged thyroids. Both of these towns are within 30 miles of Detroit. The water supply at Mount Clemens was found to contain 25 parts of iodine per billion, while at Romeo the water supply contained not a trace of iodine in 50 liters. This variation in iodine content can undoubtedly be taken as an indication that iodine percentages must vary in water and foods throughout goiter areas as well as throughout the world, just as do other soluble salts commonly found in water and food. One might surmise that the process of washing soluble

salts out of the earth's surface down into the ocean goes steadily on and that endemic goiter areas are probably increasing in size through the centuries, just as the farmer's soil is depleted of valuable elements by his crops unless they are regularly replaced by the proper fertilizers

EXPERIENCE IN MICHIGAN

Almost thirteen years has passed since the introduction of salt containing iodine and it is now possible to check on the results of its use. Through cooperation of the Michigan State Medical Society, the state board of health, Dr O P Kimball and the salt manufacturers, iodized salt was introduced in 1924 through the grocery stores without any legislation. Wide publicity of this effort was obtained at that time through letters from the state board of health to school children, parents and various organizations. In the clinic of the Henry Ford Hospital we had been treating, as had others, for a number of years previous to 1924, nontoxic diffuse goiter (simple colloid) in children with sodium iodide tablets with such uniformly good results and no ill effects that we believed in the probable efficacy of iodized salt distributed in this manner if it was universally adopted by the consuming public.

Iodized salt in Michigan contains 0.01 per cent of sodium iodide. The committee from the pediatric section of the state society, of which I am now a member, recommended that the use of this iodized salt alone should preclude the administration of any other form of iodine and that, to be effective, it should be used for cooking as well as for table use. The salt producers estimated that each inhabitant of Michigan on the average consumed between 5 and 6 pounds of salt a year, whereas other estimates placed the consumption at 8 pounds a year for each individual. The committee accepted the 8 pounds a year as a safe average. This would give the average consumer about 1 mg of sodium iodide daily.

Letters received from the largest salt distributors in Michigan show that, from 1930 to 1935 inclusive, about 85 per cent of all the salt sold was iodized salt as compared to 15 per cent of plain free running salt.

For a few years after the publicity in this matter our patients knew when asked if they were or were not using iodized salt. Today without publicity the average citizen does not know, as a rule, whether he is or is not using iodized salt. The danger today is that

without publicity a decreasing use of iodized salt may result. However, the largest salt distributors and grocery men have been our staunch allies in putting across this public health job without any law being enacted.

In Detroit today, owing mainly to the lack of publicity a decreasing amount of iodized salt is being sold by some grocers. This is partly due to the slightly higher cost of iodized salt. With this decreased sale

of iodized salt there is an increasing amount of enlarged thyroids among school children as well as in operating rooms.

In 1927 in our clinic there was a gradually increasing number of goiter patients coming to operation in spite of or perhaps because of the introduction of iodized salt. The large majority of the cases were of toxic nodular goiter and I¹ reported the results at that time. The rising curve of operations and the goiter death rate curve in Detroit suggested that the iodine might be harmful and that the earlier experience in Switzerland and in France which resulted in giving up the use of iodine was correct. However, the iodized salt sales were under such headway that there could be no discouraging its use.

During the next few years the number of goiter operations in our clinic fell off so rapidly in spite of an increasing total number of all operations that I was led to ask the seven largest hospitals in southern Michigan for their statistics. These included University Hospital, Ann Arbor, Harper, Grace, Henry Ford and Receiving hospitals, Detroit, and Blodgett Memorial and Butterworth hospitals, Grand Rapids. Their figures have been during the years freely given to us and curves plotted of each of these and then a composite curve made.

This curve shows exactly the same results that we were having in our clinic. In the seven hospitals there were only 591 goiter operations in 1933 as compared to 1,452 such operations in 1927, while the total number of all operations during the depression years dropped, a 60 per cent drop in goiter surgery compared to 17 per cent drop in all surgical operations.

It has been suggested that the decrease in the amount of goiter might be due to the depression diets, but a study of our curves show that the decline in the number of goiters started four years before the depression peak and has remained down with the return of prosperity as the total number of all operations was rising.

The yearly death rate from goiter supplied to us through the courtesy of the Detroit Board of Health suggests too that there was some harmful effect the first few years after the introduction of iodized salt (chart 3). It should be noticed that the death rate is lower than before the introduction of iodized salt for the greatly increased (doubled) population of Detroit in the eighteen years shown.

In 1924, 35 per cent of all the Detroit school children showed enlargement of the thyroid gland.² In 1932 only about 1 per cent had any such enlargement. McClendon,³ from the draft board statistics has shown

3 McClendon J F and Williams Agnes Simple Goiter as Result of Iodine Deficiency J A M A 80 690 691 (March 3) 1933 McClendon J F and Hathaway I C Inverse Relation Between Iodine in Food and Drink and Goiter Simple and Exophthalmic Ibid 82 1668 1672 (May 24) 1924

that the incidence of exophthalmic goiter throughout the United States is proportional in every locality to the incidence of endemic goiter. These two statements have been borne out by the observations reported here. In this region since the introduction of iodized salt, coincident with the great dropping off in the number of enlarged thyroids, there has been a corresponding diminution in the number of thyroid operations for hyperplasia and adenomas of the thyroid gland.

The most striking chart presented here (chart 4) is that showing the incidence of goiter or enlarged thyroid glands in the children in Detroit schools. These examinations were conducted by Kimball and the Detroit Board of Health.

As shown in the charts, the first year after the introduction of iodized salt in Michigan the rising curve suggested a possible harmful effect, and if the iodized salt had been stopped at that time the latter striking drop in the curve would not have been observed. Kocher⁴ in 1904 had warned against the indiscriminate use of iodine because of symptoms of hyperthyroidism in the adenomatous or nodular type of goiter. Kocher⁵ in 1910 and 1911 in papers on jodbasedow told of the untoward effects of iodine in exophthalmic goiter. The very name, i.e., iodine hyperthyroidism, fixed in the minds of his followers the possible dangers of iodine in the treatment of goiter.

From Cleveland in 1926 Hartsock⁶ reported that many persons with goiter are precipitated into a state of hyperthyroidism by the use of iodized salt, but he wrote to me in August 1933 "At the present time we doubt very much if we see any cases that are of this nature, i.e., iodine hyperthyroidism."⁷ This Dr Hartsock again confirms in 1937 by letter to me.

Cowie of Ann Arbor has been especially interested, as one of the responsible committee, in investigating several cases of hyperthyroidism supposed to have been induced by the use of iodized salt. He reports "We have run down several reports of ill effects from the use of iodized salt, but in each instance we have found that the reports were fallacious."

Can iodine hyperthyroidism be produced in an individual with a normal thyroid with enormous doses of iodine? We believe that this does not occur. We quote reports from two large divisions of syphilis where patients receive huge doses of iodine. Dr J E Moore of the Division of Syphilis of the Department of Medicine at the Johns Hopkins Hospital reports to me that they have records of over 20,000 patients treated with large doses of iodides with no record of a patient developing iodine hyperthyroidism. Dr Frank Menagh

Chart 4—Incidence of goiter in Detroit schools (Dr O P Kimball)

of the Henry Ford Hospital reports to me that among 6,000 cases of syphilis treated with large doses of iodides there was only one patient who presented symptoms suggestive of iodine hyperthyroidism and this was very questionable. These patients in our syphilis clinic were, of course, living in an endemic goiter region, so many had mild simple goiter.

Marine and Kimball⁹ reported "The administration of any salt or iodine in any manner completely protects the remaining thyroid against compensatory hyperplasia."

COMMENT

In view of our striking results we are led to believe that perhaps some of the goiters that we are now seeing may be due to a disturbed iodine metabolism. It might seem that the patient was taking by mouth sufficient iodine to prevent the thyroid enlargement. However, in our area it may happen that the patient does not like salt with his food or may have a prejudice against iodized salt. Then, too, as in a goiter belt the iodine content of the water varies as it does in nongoitrous areas, in a small locality the more closely confined persons in that area may have a diet deficient in iodine.

In 1928 Marine¹⁰ reported "As a result of the numerous studies of the relation of iodine to the thyroid gland our present views regarding the cause of goiter assume that it is a compensatory hypertrophy of the thyroid depending on a relative or absolute deficiency of iodine. This deficiency of iodine may be due to (1) factors which bring about an abnormally low intake of iodine, (2) factors which interfere with the absorption or utilization of an otherwise adequate intake, (3) factors which increase the needs of the body for the iodine containing hormone." The chief factor under 1 is the lack of iodine in the food and water supply. Factors under 2 are not so well known although there have been recent papers on this subject.

- 9 Marine David and Kimball O P Prevention of Simple Goiter Man J A M A 77: 1068 (Oct 1) 1921
 10 Marine David Chemistry in Medicine New York Chemical Foundation Inc 1928 p 272

Under 3 it is well known that the thyroid is prone to enlarge at puberty, at menstruation, during pregnancies and sometimes in cases of malnutrition and with infections

It would appear that iodine metabolism is very closely related to the problem of thyroid dysfunction¹¹

CONCLUSIONS

1 There is no doubt that there is a deficiency of iodine in the diet of the inhabitants of Michigan. To combat this it is safe and sound in some way to add more than enough iodine to the diet. In Michigan iodized salt has been chosen at the present time as the most practical way.

2 Iodized salt as used in Michigan did at first apparently increase the number of thyroid operations.

3 The increase occurred in the nodular goiter or adenoma group, and we believe the iodized salt may have activated a group of patients with quiescent adenomas, producing toxic goiter symptoms.

4 The increase reached its peak in the second year after the introduction of iodized salt.

5 An increase in the death rate from goiter as shown by the board of health statistics reached its peak in the second year after the introduction of iodized salt.

6 There was no increase in hyperthyroidism excepting in the nodular goiter or adenoma group.

7 The number of operations for toxic diffuse and toxic nodular goiter has rapidly and steadily decreased after the apex of the second year excepting for a slight increase during the last three years.

8 The incidence of endemic goiter or enlarged thyroid has been reduced almost to nil since iodized salt has been so widely used.

9 We now see no cases which show the slightest ill effects from the use of iodized salt.

10 Toxic nodular goiter and toxic diffuse goiter are less apt to occur when there has been no previous enlargement of the thyroid (endemic goiter), at least this would seem a safe conclusion based on our experience.

11 As the publicity concerning the necessity for the use of iodized salt has fallen off, the sales of iodized salt have decreased until today one of the larger retail dealers in Detroit sells only about 50 per cent of iodized salt. Others range in sales up to 75 per cent, while the average is 75 per cent.¹² Our charts, reproduced here, show the result of this delinquency by a slight rise in the number of goiters in our school children and in our operating rooms. To combat this slump, either continued publicity must be given to this subject or should a law be passed making it mandatory for grocers to sell only iodized salt?

Clinical Notes, Suggestions and New Instruments

CHRONIC ARACHNOIDITIS OBLITERATING THE SPINAL SUBARACHNOID SPACE

LEWELLIS F. BARKER, M.D., AND FRANK R. FORD, M.D., BALTIMORE

Though the choriomeningitis of human beings that is due to the virus of Rivers and Scott is usually a relatively mild malady ending in complete recovery—so mild indeed that it is often designated 'acute benign lymphocytic meningitis'—the case to be reported here indicates that it may sometimes be followed by a severe chronic arachnoiditis which causes widespread obliteration of the spinal subarachnoid space.

Florence A., a white woman now 37 years of age, suffered from an attack of lymphocytic meningitis in February 1936.

Aside from a trauma of the head some thirteen years earlier from which she had made a good recovery, her previous history had been uneventful.

About two weeks before her admission to the Johns Hopkins Hospital in February 1936 she lost her appetite and complained of sore throat, general sensitiveness, aching pains and fever (temperature of 103 F). She became irrational, had a convulsive seizure and since she was pregnant, was admitted to the obstetric service, where on lumbar puncture it was found that the cerebrospinal fluid contained 500 white cells, 90 per cent of which were lymphocytes. She was transferred to the Osler Medical Ward (service of Dr. W. T. Longcope) for further study and treatment. She continued to have slight fever, an abortion occurred, and bilateral parotitis developed. For a time there was doubt as to whether she was suffering from a 'mumps encephalomyelitis' or from 'benign lymphocytic meningitis associated with parotitis.' Some of the spinal fluid was sent to the Rockefeller Institute and in it the virus of lymphocytic meningitis (Rivers and Scott) was shown to be present. Cultures from Steno's ducts showed that the parotitis was due to *Staphylococcus aureus*.

When convalescence set in she seemed to do well at first, but later there was nausea, vomiting, difficulty in urination and a convulsive seizure. During the early part of the summer she gradually lost motor power in the lower half of the body and sensory disturbances developed (all modalities) from the level of the fourth thoracic segment downward. Repeated lumbar punctures were attempted but no cerebrospinal fluid could be obtained, nor did any fluid flow out when cisternal puncture was done. It was possible, however, to inject some iodized poppy-seed oil into the cisterna and on x-ray examination it was shown that this iodized oil did not trickle farther downward than the level of the fifth thoracic segment, where it underwent complete block.

In July Dr. Walter Dandy explored the lower thoracic cord removing the posterior portions of the fourth, fifth, sixth and seventh thoracic vertebrae. Below the dura was a thick fibrous mass attached to the spinal cord upward and downward throughout the whole area explored, completely obliterating the subarachnoid space in the region examined.

After recovery from this operation she walked with the aid of crutches for a time but in November she suffered from an attack of influenza, after which she found herself totally unable to move the lower extremities, she suffered from dysuria and continued to be numb from the waist downward.

At the present time (the early part of March 1937), the patient exhibits complete spastic paralysis from the level of the umbilicus downward with patellar and ankle clonus. The abdominal reflexes are absent. The bladder remains partially distended after urination. Sensory disturbances below the level of the fourth thoracic segment are marked: pain, temperature and vibratory sensations are absent, tactile stimuli yield no response between the levels of the fourth thoracic and the first lumbar and response is only slight from the first lumbar downward.

It would seem obvious that the clinical picture must be due to the severe chronic arachnoiditis with involvement of the spinal cord and posterior roots demonstrated by Dr. Dandy at his exploratory operation and it would seem most probable that this chronic arachnoiditis has been a direct sequel of the

acute lymphocytic meningitis of February 1936, which was proved to be due to the minute ultramicroscopic virus of Rivers and Scott. No case precisely like this appears as yet to have been recorded in the literature of lymphocytic meningitis, though cases of circumscribed chronic leptomeningitis causing pseudocerebral tumors were reported last year by de Martel, Guillaume and Thurel.¹

The surgical aspects of chronic arachnoiditis have been discussed by Stookey,² and the ameliorative effects of treatment by high voltage roentgen therapy have been reported by Selinsky.³
